[DeviceB-GigabitEthernet1/0/1] ipv6 nd raguard role host
[DeviceB-GigabitEthernet1/0/1] quit
```

Specify **router** as the role of the device attached to GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ipv6 nd raguard role router
[DeviceB-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify that the device forwards or drops RA messages received on GigabitEthernet 1/0/2 based on the RA guard policy. (Details not shown.)

Verify that the device drops RA messages received on GigabitEthernet 1/0/1. (Details not shown.)

Verify that the device forwards RA messages received on GigabitEthernet 1/0/3 to other interfaces in VLAN 10. (Details not shown.)

Configuring SAVI

About SAVI

Source Address Validation Improvement (SAVI) checks the validity of the source addresses of global unicast IPv6 packets. It implements the validity check by using the ND snooping, DHCPv6 snooping, ND attack detection, and IP source guard features. SAVI checks only global unicast addresses and forwards the packets that pass the validity check. Packets sourced from an invalid address are dropped.

SAVI application scenarios

DHCPv6-only

The hosts connected to the SAVI-enabled device obtain addresses only through DHCPv6. DHCPv6 messages, ND messages (RA and RR messages excluded), and IPv6 data packets are checked based on DHCPv6 snooping entries and static IPv6 source guard binding entries.

SLAAC-only

The hosts connected to the SAVI-enabled device obtain addresses only through Stateless Address Autoconfiguration (SLAAC). In this scenario, SAVI drops all DHCPv6 messages. Only ND messages and IPv6 data packets are checked based on DHCPv6 snooping entries and static IPv6 source guard binding entries.

DHCPv6+SLAAC

The hosts connected to the SAVI-enabled device obtain addresses through DHCPv6 and SLAAC. In this scenario, SAVI checks all DHCPv6 messages, ND messages, and IPv6 data packets based on DHCPv6 snooping entries, ND snooping entries, and static IPv6 source guard binding entries.

SAVI tasks at a glance

To configure SAVI, perform the following tasks:

1. Enabling SAVI
2. Configuring IPv6 source guard
3. Configuring DHCPv6 snooping
4. Configuring ND parameters
5. (Optional.) Setting the entry deletion delay
6. (Optional.) Enabling

Enabling SAVI

1. Enter system view.
   `system-view`
2. Enable SAVI.
   `ipv6 savi strict`
   By default, SAVI is disabled.

Configuring IPv6 source guard

1. Enable IPv6 source guard on an interface.
2. (Optional.) Configure static IPv6SG bindings.

For more information about IPv6 source guard configuration, see "Configuring IP source guard."

Configuring DHCPv6 snooping

Restrictions and guidelines

Enable only DHCPv6 snooping for the SLAAC-only scenario.

Procedure

1. Enable DHCPv6 snooping.
2. Specify DHCPv6 snooping trusted ports.
3. Enable recording client information in DHCPv6 snooping entries.

For more information about DHCPv6 snooping configuration, see *Layer 3—IP Services Configuration Guide*.

Configuring ND parameters

Restrictions and guidelines

Enable only ND attack detection for the DHCPv6-only scenario.

Procedure

1. Enable ND snooping for global unicast addresses.

   For more information about ND snooping, see IPv6 basics in *Layer 3—IP Services Configuration Guide*.
2. Enable ND attack detection.

   For more information about ND attack detection, see "Configuring ND attack defense."
3. Specify ND trusted ports.

   For more information about ND trusted ports, see "Configuring ND attack defense."

Setting the entry deletion delay

About this task

The entry deletion delay is the period of time that the device waits before deleting the DHCPv6 snooping entries and ND snooping entries for a down port.

Procedure

1. Enter system view.

   system-view
2. Set the entry deletion delay.

   ipv6 savi down-delay *delay-time*

   By default, the entry deletion delay is 30 seconds.

Enabling filtering entry logging

About this task

Filtering entries are effective bindings used for filtering IPv6 packets by the source IPv6 address. Filtering entry logging enables the device to generate log messages for filtering entries. A log message contains the IPv6 address, MAC address, VLAN, and interface of a filtering entry.

The device sends filtering entry log messages to the information center. With the information center, you can set log message filtering and output rules, including output destinations. For more information about using the information center, see *Network Management and Monitoring Configuration Guide*.

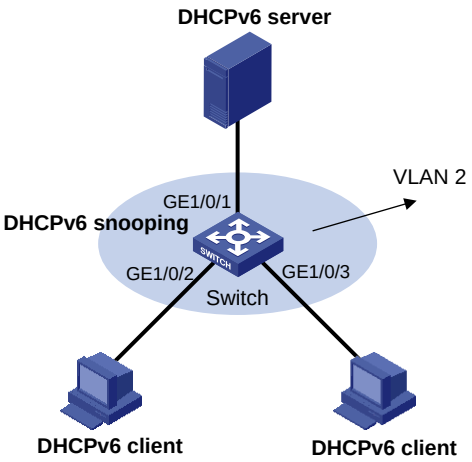
Feature and software compatiblity

This feature is available only in Release 1107 or later.

Procedure

1. Enter system view.
   `system-view`
2. Enable filtering entry logging.
   `ipv6 savi log enable filter-entry`
   By default, filtering entry logging is disabled.

SAVI configuration examples



Example: Configuring DHCPv6-only SAVI

Network configuration

As shown in Figure 1, configure SAVI on the switch to meet the following requirements:

- Clients obtain IPv6 addresses only through DHCPv6.
- SAVI checks the source addresses of DHCPv6 messages, ND messages (RA and RR messages excluded), and IPv6 data packets on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

Figure 1 Network diagram

Procedure

Enable SAVI.

```
<Switch> system-view
[Switch] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to VLAN 2.

```
[Switch] vlan 2
[Switch-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
[Switch-vlan2] quit
```

Enable DHCPv6 snooping.

```
[Switch] ipv6 dhcp snooping enable
```

Configure GigabitEthernet 1/0/1 as a DHCPv6 snooping trusted port.

```
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[Switch-GigabitEthernet1/0/1] quit
```

Enable recording DHCPv6 snooping entries on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

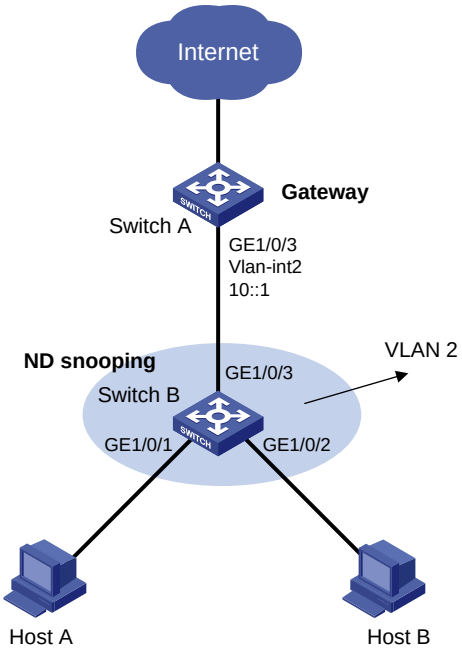
```
[Switch] interface gigabitethernet 1/0/2
[Switch-GigabitEthernet1/0/2] ipv6 dhcp snooping binding record
[Switch-GigabitEthernet1/0/2] quit
[Switch] interface gigabitethernet 1/0/3
[Switch-GigabitEthernet1/0/3] ipv6 dhcp snooping binding record
[Switch-GigabitEthernet1/0/3] quit
```

Enable ND attack detection.

```
[Switch] vlan 2
[Switch-vlan2] ipv6 nd detection enable
[Switch-vlan2] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

```
[Switch] interface gigabitethernet 1/0/2
[Switch-GigabitEthernet1/0/2] ipv6 verify source ip-address mac-address
[Switch-GigabitEthernet1/0/2] quit
[Switch] interface gigabitethernet 1/0/3
[Switch-GigabitEthernet1/0/3] ipv6 verify source ip-address mac-address
[Switch-GigabitEthernet1/0/3] quit
```



Example: Configuring SLAAC-only SAVI

Network configuration

As shown in Figure 2, configure SAVI on Switch B to meet the following requirements:

- Hosts obtain IPv6 addresses only through SLAAC.
- DHCPv6 messages are dropped on GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 in VLAN 2.
- SAVI checks the source addresses of ND messages and IPv6 data packets on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

Figure 2 Network diagram

Procedure

Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
[SwitchB-vlan2] quit
```

Enable ND snooping for global unicast addresses in VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] ipv6 nd snooping enable global
```

Enable ND attack detection for VLAN 2.

```
[SwitchB-vlan2] ipv6 nd detection enable
[SwitchB-vlan2] quit
```

Enable DHCPv6 snooping.

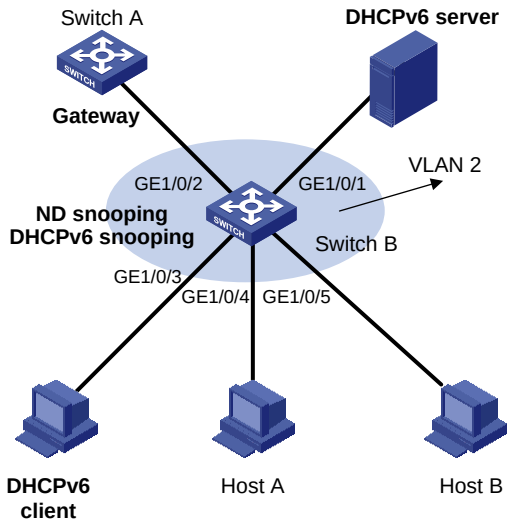
```
[SwitchB] ipv6 dhcp snooping enable
```

Configure GigabitEthernet 1/0/3 as an ND trusted port.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 nd detection trust
[SwitchB-GigabitEthernet1/0/3] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/2] quit
```



Example: Configuring DHCPv6+SLAAC SAVI

Network configuration

As shown in Figure 3, configure SAVI on Switch B to meet the following requirements:

- Hosts obtain IP addresses through DHCPv6 or SLAAC.
- SAVI checks the source addresses of DHCPv6 messages, ND messages, and IPv6 data packets on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

Figure 3 Network diagram

Procedure

Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 to VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
gigabitethernet 1/0/4 gigabitethernet 1/0/5
```

Enable DHCPv6 snooping.

```
[SwitchB] ipv6 dhcp snooping enable
```

Enable recording DHCPv6 snooping entries on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] interface gigabitethernet 1/0/4
[SwitchB-GigabitEthernet1/0/4] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/4] quit
[SwitchB] interface gigabitethernet 1/0/5
[SwitchB-GigabitEthernet1/0/5] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/5] quit
```

Configure GigabitEthernet 1/0/1 as a DHCPv6 snooping trusted port.

```
[SwitchB] interface gigabitethernet 1/0/1
```

```
[SwitchB-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

Enable ND snooping for global unicast addresses in VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] ipv6 nd snooping enable global
```

Enable ND attack detection for VLAN 2.

```
[SwitchB-vlan2] ipv6 nd detection enable
[SwitchB-vlan2] quit
```

Configure GigabitEthernet 1/0/2 as an ND trusted port.

```
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 nd detection trust
[SwitchB-GigabitEthernet1/0/2] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] interface gigabitethernet 1/0/4
[SwitchB-GigabitEthernet1/0/4] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/4] quit
[SwitchB] interface gigabitethernet 1/0/5
[SwitchB-GigabitEthernet1/0/5] ipv6 verify source ip-address mac-address
```

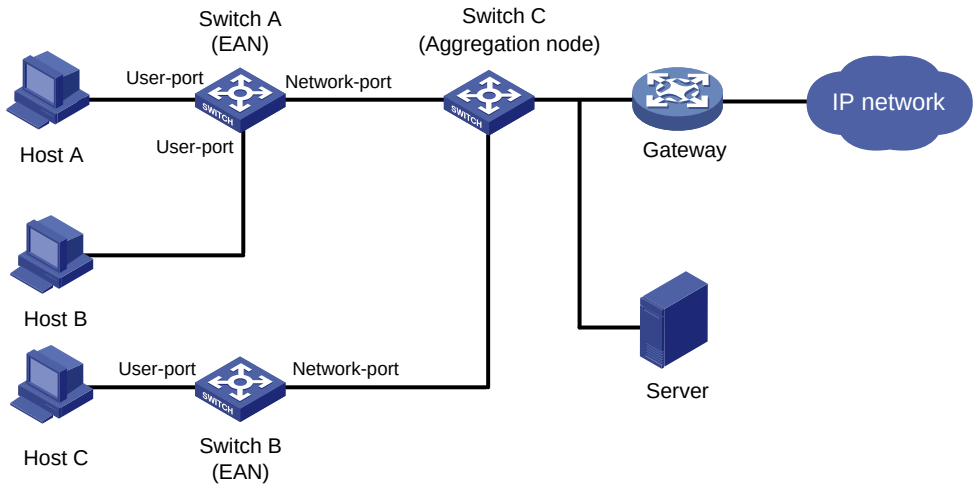
Configuring MFF

About MFF



MAC-forced forwarding (MFF) implements Layer 2 isolation and Layer 3 communication between hosts in the same broadcast domain.

An MFF-enabled device intercepts ARP requests and returns the MAC address of a gateway (or server) to the senders. In this way, the senders are forced to send packets to the gateway for traffic monitoring and attack prevention.

MFF network model

As shown in Figure 1, hosts are connected to Switch C through Switch A and Switch B, which are called Ethernet access nodes (EANs). The MFF-enabled EANs forward packets from hosts to the gateway for further forwarding. The hosts are isolated at Layer 2, but they can communicate at Layer 3.

Figure 1 Network diagram for MFF

MFF works with any of the following features to implement traffic filtering and Layer 2 isolation on the EANs:

- ARP snooping (see *Layer 3—IP Services Configuration Guide*).
- IP source guard (see "Configuring IP source guard").
- ARP detection (see "Configuring ARP attack protection").
- VLAN mapping (see *Layer 2—LAN Switching Configuration Guide*).

Port roles

Two types of ports, user port and network port, exist in an MFF-enabled VLAN.

User port

An MFF user port is directly connected to a host and processes the following packets differently:

- Allows multicast packets to pass.
- Delivers ARP packets to the CPU.

- Processes unicast packets as follows:
  - If gateways' MAC addresses have been learned, the user port allows only the unicast packets with the gateways' MAC addresses as the destination MAC addresses to pass.
  - If no gateways' MAC addresses have been learned, the user port discards all received unicast packets.

Network port

An MFF network port is connected to any of the following networking devices:

- An access switch.
- A distribution switch.
- A gateway.
- A server.

A network port processes the following packets differently:

- Allows multicast packets to pass.
- Delivers ARP packets to the CPU.
- Denies broadcast packets other than DHCP and ARP packets.

Processing of ARP packets in MFF

An MFF-enabled device implements Layer 3 communication between hosts by intercepting ARP requests from the hosts and replies with the MAC address of a gateway. This mechanism helps reduce the number of broadcast messages.

The MFF device processes ARP packets as follows:

- After receiving an ARP request from a host, the MFF device sends the MAC address of the corresponding gateway to the host. In this way, hosts in the network have to communicate at Layer 3 through a gateway.
- After receiving an ARP request from a gateway, the MFF device sends the requested host's MAC address to the gateway if the corresponding entry is available. If the entry is not available, the MFF device forwards the ARP request.
- The MFF device forwards ARP replies between hosts and gateways.
- If the source MAC addresses of ARP requests from gateways are different from those recorded, the MFF device updates and broadcasts the IP and MAC addresses of the gateways.

MFF default gateway

MFF applies to only networks where the hosts' IP addresses are manually configured. Because the hosts cannot obtain the gateway information through DHCP, the default gateway must be specified by the **`mac-forced-forwarding default-gateway`** command. MFF maintains only one default gateway for each VLAN. MFF updates the MAC address of the default gateway upon receiving an ARP packet with a different sender MAC address from the default gateway.

Protocols and standards

RFC 4562, *MAC-Forced Forwarding*

MFF tasks at a glance

To configure MFF, perform the following tasks:

1. Enabling MFF
2. Configuring a network port
3. (Optional.) Enabling periodic gateway probe
4. Specifying the IP addresses of servers

   If servers exist in the network, you must perform this task to ensure communication between the servers and hosts.

Enabling MFF

Restrictions and guidelines

- An MFF-enabled device and a host cannot ping each other.
- When MFF works with static IP source guard bindings, you must configure VLAN IDs in the static bindings. Otherwise, IP packets allowed by IP source guard are permitted even if their destination MAC addresses are not the MAC address of the gateway.
- MFF is not supported in a network where VRRP load balancing mode is configured.

Prerequisites

For MFF to take effect, make sure ARP snooping is enabled on the VLAN where MFF is enabled.

Procedure

1. Enter system view.

   system-view
2. Enter VLAN view.

   vlan *vlan-id*
3. Enable MFF.

   mac-forced-forwarding default-gateway *gateway-ip*

   By default, MFF is disabled.

Configuring a network port

Restrictions and guidelines

In a VLAN with MFF enabled, you need to configure the following ports as network ports:

- Upstream ports connected to the gateway.
- Ports connected to other MFF devices.

Link aggregation is supported by network ports in an MFF-enabled VLAN, but it is not supported by user ports in the VLAN. You can add the network ports to link aggregation groups, but cannot add the user ports to link aggregation groups. For more information about link aggregation, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the port as a network port.

   mac-forced-forwarding network-port

   By default, the port is a user port.

Enabling periodic gateway probe

About this task

You can configure the MFF device to detect gateways every 30 seconds for the change of MAC addresses by sending forged ARP packets. The ARP packets use 0.0.0.0 as the sender IP address and bridge MAC address as the sender MAC address.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable periodic gateway probe.
   mac-forced-forwarding gateway probe
   By default, this feature is disabled.

Specifying the IP addresses of servers

About this task

Server IP addresses can be those of the interfaces on a router in a VRRP group and those of the servers collaborating with MFF, such as a RADIUS server.

When the MFF device receives an ARP request from a server, the device searches IP-to-MAC address entries it has stored. Then the device replies with the requested MAC address to the server.

As a result, packets from a host to a server are forwarded by the gateway. However, packets from a server to a host are not forwarded by the gateway.

MFF does not check whether the IP address of a server is on the same network segment as that of a gateway. Instead, it checks whether the IP address of a server is all-zero or all-one. An all-zero or all-one server IP address is invalid.

Restrictions and guidelines

If the server's interface connecting to the MFF device uses secondary IP addresses to send ARP packets, include all these IP addresses in the server IP address list.

Procedure

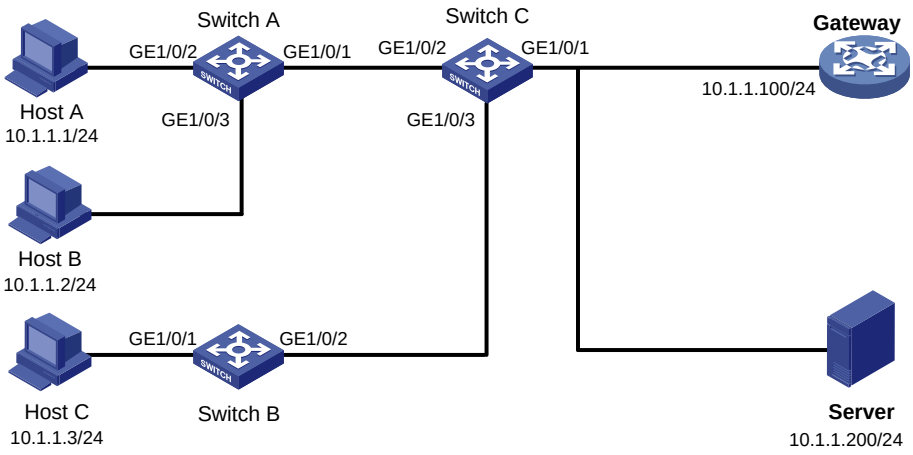
1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Specify the IP addresses of servers.
   mac-forced-forwarding server *server-ip*&<1-10>
   By default, no server IP address is specified.

Display and maintenance commands for MFF

Execute **display** commands in any view.

Task	Command
Display MFF port configuration.	**display mac-forced-forwarding interface**
Display the MFF configuration for a VLAN.	**display mac-forced-forwarding vlan** *vlan-id*

MFF configuration examples



Example: Configuring MFF in a tree network

Network configuration

As shown in Figure 2, all the devices are in VLAN 100. Hosts A, B, and C are assigned IP addresses manually.

Configure MFF to isolate the hosts at Layer 2 and allow them to communicate with each other through the gateway at Layer 3.

Figure 2 Network diagram

Procedure

1. Configure the IP addresses of the hosts and the gateway, as shown in Figure 2.
2. Configure Switch A:

   # Configure MFF on VLAN 100.

   ```
   [SwitchA] vlan 100
   [SwitchA-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
   ```

   # Specify the IP address of the server.

   ```
   [SwitchA-vlan100] mac-forced-forwarding server 10.1.1.200
   ```

   # Enable ARP snooping on VLAN 100.

   ```
   [SwitchA-vlan100] arp snooping enable
   [SwitchA-vlan100] quit
   ```

   # Configure GigabitEthernet 1/0/1 as a network port.

   ```
   [SwitchA] interface gigabitethernet 1/0/1
   [SwitchA-GigabitEthernet1/0/1] mac-forced-forwarding network-port
   ```
3. Configure Switch B:

Configure MFF on VLAN 100.

```
[SwitchB] vlan 100
[SwitchB-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
```

Specify the IP address of the server.

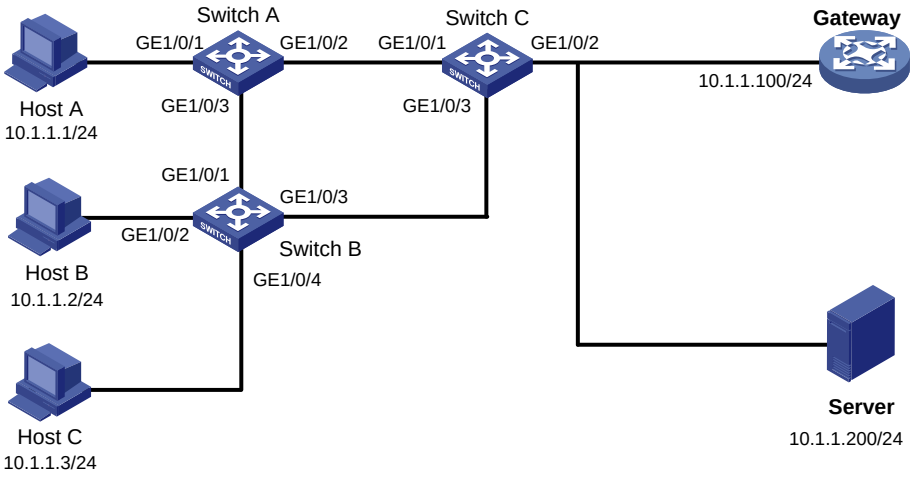
```
[SwitchB-vlan100] mac-forced-forwarding server 10.1.1.200
```

Enable ARP snooping on VLAN 100.

```
[SwitchB-vlan100] arp snooping enable
[SwitchB-vlan100] quit
```

Configure GigabitEthernet 1/0/2 as a network port.

```
[SwitchB] interface gigabitethernet 1/0/2 1/0/6
[SwitchB-GigabitEthernet1/0/2] mac-forced-forwarding network-port
```



Example: Configuring MFF in a ring network

Network configuration

As shown in Figure 3, all the devices are in VLAN 100, and the switches form a ring. Hosts A, B, and C are assigned IP addresses manually.

Configure MFF to isolate the hosts at Layer 2 and allow them to communicate with each other through the gateway at Layer 3.

Figure 3 Network diagram

Procedure

1. Configure the IP addresses of the hosts and the gateway, as in shown in Figure 3.
2. Configure Switch A:

   # Enable STP globally to make sure STP is enabled on interfaces.

   ```
   [SwitchA] stp global enable
   ```

   # Configure MFF on VLAN 100.

   ```
   [SwitchA] vlan 100
   [SwitchA-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
   ```

   # Specify the IP address of the server.

   ```
   [SwitchA-vlan100] mac-forced-forwarding server 10.1.1.200
   ```

   # Enable ARP snooping on VLAN 100.

   ```
   [SwitchA-vlan100] arp snooping enable
   ```

```
[SwitchA-vlan100] quit
```

Configure GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 as network ports.

```
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] mac-forced-forwarding network-port
[SwitchA-GigabitEthernet1/0/2] quit
[SwitchA] interface gigabitethernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] mac-forced-forwarding network-port
```

3. Configure Switch B:

Enable STP globally to make sure STP is enabled on interfaces.

```
[SwitchB] stp global enable
```

Configure MFF on VLAN 100.

```
[SwitchB] vlan 100
[SwitchB-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
```

Specify the IP address of the server.

```
[SwitchB-vlan100] mac-forced-forwarding server 10.1.1.200
```

Enable ARP snooping on VLAN 100.

```
[SwitchB-vlan100] arp snooping enable
[SwitchB-vlan100] quit
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/3 as network ports.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] mac-forced-forwarding network-port
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] mac-forced-forwarding network-port
```

4. Enable STP on Switch C globally to make sure STP is enabled on interfaces.

```
<SwitchC> system-view
[SwitchC] stp global enable
```

Configuring crypto engines 1
About crypto engines 1
Display and maintenance commands for crypto engines 1

Configuring crypto engines

About crypto engines

Crypto engines encrypt and decrypt data for service modules.

The device supports only one software crypto engine, which is a set of software encryption algorithms. The software crypto engine is always enabled.

When a service module requires data encryption/decryption, it sends the desired data to the crypto engine. After the crypto engine completes data encryption/decryption, it sends the data back to the service module.

Display and maintenance commands for crypto engines

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display crypto engine information.	**display crypto-engine**
Display crypto engine statistics.	**display crypto-engine statistics** [**engine-id** *engine-id* **slot** *slot-number*]
Clear crypto engine statistics.	**reset crypto-engine statistics** [**engine-id** *engine-id* **slot** *slot-number*]

Configuring FIPS

About FIPS

Federal Information Processing Standards (FIPS) was developed by the National Institute of Standards and Technology (NIST) of the United States. FIPS specifies the requirements for cryptographic modules.

FIPS security levels

FIPS 140-2 defines four levels of security, named Level 1 to Level 4, from low to high. The device supports Level 2.

Unless otherwise noted, the term "FIPS" refers to Level-2 FIPS 140-2 in this document.

FIPS functionality

In FIPS mode, the device has strict security requirements. It performs self-tests on cryptography modules to verify that the modules are operating correctly.

A FIPS device also meets the functionality requirements defined in Network Device Protection Profile (NDPP) of Common Criteria (CC).

FIPS self-tests

To ensure correct operation of cryptography modules, FIPS provides self-test mechanisms, including power-up self-tests and conditional self-tests.

If a power-up self-test fails, the device where the self-test process exists reboots. If a conditional self-test fails, the system outputs a self-test failure message.

NOTE:

If a self-test fails, contact H3C Support.

Power-up self-tests

The power-up self-test examines the availability of FIPS-allowed cryptographic algorithms.

The device supports the following types of power-up self-tests:

- Known-answer test (KAT)

  A cryptographic algorithm is run on data for which the correct output is already known. The calculated output is compared with the known answer. If they are not identical, the KAT test fails.

- Pairwise conditional test (PWCT)
  - **Signature and authentication test**—The test is run when a DSA, RSA, or ECDSA asymmetrical key pair is generated. The system uses the private key to sign the specific data, and then uses the public key to authenticate the signed data. If the authentication is successful, the test succeeds.
  - **Encryption and decryption test**—The test is run when an RSA asymmetrical key pair is generated. The system uses the public key to encrypt a plain text string, and then uses the private key to decrypt the encrypted text. If the decryption result is the same as the original plain text string, the test succeeds.

The power-up self-test examines the cryptographic algorithms listed in Table 1.

Table 1 Power-up self-tests list

Type	Operations
KAT	Tests the following algorithms: • SHA1, SHA224, SHA256, SHA384, and SHA512. • HMAC-SHA1, HMAC-SHA224, HMAC-SHA256, HMAC-SHA384, and HMAC-SHA512. • AES. • RSA (signature and authentication). • ECDH. • DRBG. • GCM. • GMAC.
PWCT	Tests the following algorithms: • RSA (signature and authentication). • RSA (encryption and decryption). • DSA (signature and authentication). • ECDSA (signature and authentication).

Conditional self-tests

A conditional self-test runs when an asymmetrical cryptographic module or a random number generator module is invoked. Conditional self-tests include the following types:

- **PWCT signature and authentication**—This test is run when a DSA or RSA asymmetrical key pair is generated. The system uses the private key to sign the specific data, and then uses the public key to authenticate the signed data. If the authentication is successful, the test succeeds.
- **Continuous random number generator test**—Runs when a random number is generated. The system compares the generated random number with the previously generated random number. If the two numbers are the same, the test fails. This test also runs when a DSA or RSA asymmetrical key pair is generated.

Restrictions and guidelines: FIPS

Requirements for key pairs and passwords

Before you reboot the device to enter FIPS mode, the system automatically removes all key pairs configured in non-FIPS mode and all FIPS-incompliant digital certificates. FIPS-incompliant digital certificates are MD5-based certificates with a key modulus length less than 2048 bits. You cannot log in to the device through SSH after the device enters FIPS mode. To log in to the device in FIPS mode through SSH, log in to the device through a console port and create a key pair for the SSH server.

The password for entering the device in FIPS mode must comply with the password control policies, such as password length, complexity, and aging policy. When the aging timer for a password expires, the system prompts you to change the password. If you adjust the system time after the device enters FIPS mode, the login password might expire before the next login, because the original system time is typically much earlier than the actual time.

Configuration rollback guidelines

Configuration rollback is supported in FIPS mode and also during a switch between FIPS mode and non-FIPS mode. After a configuration rollback between FIPS mode and non-FIPS mode, perform the following tasks:

1. Delete the local user and configure a new local user. Local user attributes include password, user role, and service type.

2. Save the current configuration file.
3. Specify the current configuration file as the startup configuration file.
4. Reboot the device. The new configuration takes effect after the reboot. During this process, do not exit the system or perform other operations.

If a device enters FIPS or non-FIPS mode through automatic reboot, configuration rollback fails. To support configuration rollback, you must execute the **save** command after the device enters FIPS or non-FIPS mode.

IRF compatibility

All devices in an IRF fabric must be operating in the same mode, whether in FIPS mode or non-FIPS mode.

To enable FIPS mode for an IRF fabric, you must reboot the entire IRF fabric.

Feature changes in FIPS mode

After the system enters FIPS mode, the following feature changes occur:

- The user login authentication mode can only be scheme.
- The FTP/TFTP server and client are disabled.
- The Telnet server and client are disabled.
- The HTTP server is disabled.
- SNMPv1 and SNMPv2c are disabled. Only SNMPv3 is available.
- The SSL server supports only TLS1.0, TLS1.1, and TLS1.2.
- The SSH server does not support SSHv1 clients or DSA key pairs.
- The generated RSA and DSA key pairs must have a modulus length of 2048 bits.

  When the device acts as a server to authenticate a client through the public key, the key pair for the client must also have a modulus length of 2048 bits.
- The generated ECDSA key pairs must have a modulus length of more than 256 bits.

  When the device acts as a server to authenticate a client through the public key, the key pair for the client must also have a modulus length of more than 256 bits.
- SSH, SNMPv3, IPsec, and SSL do not support DES, 3DES, RC4, or MD5.
- The password control feature cannot be disabled globally. The **undo password-control enable** command does not take effect.
- An AAA shared key, IKE pre-shared key, or SNMPv3 authentication key must have at least 15 characters and must contain uppercase and lowercase letters, digits, and special characters.
- The password for a device management local user and password for switching user roles must comply with the password control policies. By default, the password must have at least 15 characters and must contain uppercase and lowercase letters, digits, and special characters.

Entering FIPS mode

About entering FIPS mode

For the device to enter FIPS mode, you can use one of the following methods:

- **Automatic reboot**—The system automatically performs the following operations:
  a. Prompts you to specify the username and password for the next login.
  b. Creates a default FIPS configuration file named **fips-startup.cfg**.
  c. Specifies the default FIPS configuration file as the startup configuration file.
  d. Reboots and loads the default FIPS configuration file to enter the FIPS mode.

- **Manual reboot**—You must complete the required configuration tasks and reboot the device manually.

Restrictions and guidelines

After you execute the **`fips mode enable`** command, the system prompts you to choose a reboot method.

- If you do not make a choice within 30 seconds or press **Ctrl**+**C**, the system enables FIPS mode and waits for you to manually complete the FIPS mode configuration tasks.
- If you select the automatic reboot method, you can press **Ctrl**+**C** to abort both the interactive FIPS mode configuration process and the **`fips mode enable`** command.

Using the automatic reboot method to enter FIPS mode

Prerequisites

To ensure login password effectiveness under the password control policies, set the correct system time.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable FIPS mode.

   ```
   fips mode enable
   ```

   By default, the FIPS mode is disabled.

3. After the reboot method choice prompt appears, enter **Y** within 30 minutes.

   The system starts the interactive FIPS mode configuration process.

CAUTION:

System reboot might interrupt ongoing services. Please perform the previous operations with caution.

4. Enter the login username and password as prompted.

   The password must have a minimum of 15 characters and must contain uppercase and lowercase letters, digits, and special characters. After you enter the username and password, the device performs the following operations:

   - Creates a device management local user that uses the entered username and password.
   - Assigns the user the terminal service and the network-admin user role.
   - Saves the running configuration and specifies the configuration file as the startup configuration file.
   - Reboots, loads the startup configuration file, and enters FIPS mode.

To log in to the device, you must enter the configured username and password. After login, you are identified as the FIPS mode crypto officer.

Using the manual reboot method to enter FIPS mode

Prerequisites

1. To ensure login password effectiveness under the password control policies, set the correct system time.

2. Configure the password control feature.
   a. Enable the password control feature globally.
   b. Configure password control policies.
      - Set the number of character types a password must contain to 4.
      - Set the minimum number of characters for each type to one character.
      - Set the minimum length for a user password to 15 characters.

   For more information about the password control feature, see password control in *Security Configuration Guide*.
3. Configure a local user.
   - Create a device management local user.
   - Specify a password that complies with the password control policies.
   - Assign the terminal service to the user.
   - Assign the network-admin user role to the user.

Procedure

1. Enter system view.

   `system-view`
2. Enable FIPS mode.

   `fips mode enable`

   By default, the FIPS mode is disabled.
3. After the reboot method choice prompt appears, enter **N**.

   The system enables FIPS mode and waits for you to complete the FIPS mode configuration tasks. Before rebooting the device to enter FIPS mode, do not execute any commands except for **`save`** and commands used to prepare for entering FIPS mode. If you execute any other commands, the commands might not take effect.

   CAUTION:
   - System reboot might interrupt ongoing services. Perform this operation with caution.
   - After you select the manual reboot method to enable FIPS mode, you must manually complete the configurations for entering FIPS mode. Otherwise, you cannot log in to the system correctly.
4. Save the running configuration and specify the configuration file as the startup configuration file.
5. Delete the .mdb startup configuration file.

   When loading a .mdb configuration file, the device loads all settings in the file. The settings that are not supported in FIPS mode might affect device operation.
6. Reboot the device.

   The device reboots, loads the startup configuration file, and enters FIPS mode. To log in to the device, you must enter the configured username and password. After login, you are identified as the FIPS mode crypto officer.

Manually triggering self-tests

About this task

You can manually trigger FIPS self-tests to verify operation of cryptography modules anytime as required. The triggered self-tests are the same as the power-up self-tests.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Trigger self-tests.
   ```
   fips self-test
   ```

CAUTION:

A successful self-test requires that all cryptographic algorithms pass the self-test. If the self-test fails, the device where the self-test process exists reboots.

Exiting FIPS mode

About this task

After you disable FIPS mode and reboot the device, the device operates in non-FIPS mode.

For the device to exit FIPS mode, you can use one of the following reboot methods:

- **Automatic reboot**—The system automatically creates a default non-FIPS configuration file named **non-fips-startup.cfg**, specifies the file as the startup configuration file, and reboots to enter non-FIPS mode. You can log in to the device without providing username or password.
- **Manual reboot**—You must manually complete the configuration tasks for entering non-FIPS mode, and then reboot the device. To log in to the device after the reboot, you must enter user information as required by the authentication mode settings.

  The following are the default authentication mode settings:
  - **VTY line**—Password authentication.
  - **AUX line**—Authentication is disabled. (Devices that have only the console or AUX port.)

  You can modify the authentication settings as needed.

Using the automatic reboot method to exit FIPS mode

1. Enter system view.
   ```
   system-view
   ```
2. Disable FIPS mode.
   ```
   undo fips mode enable
   ```
   By default, the FIPS mode is disabled.
3. Select the automatic reboot method.

CAUTION:

System reboot might interrupt ongoing services. Please perform the previous operations with caution.

Using the manual reboot method to exit FIPS mode

1. Enter system view.
   ```
   system-view
   ```
2. Disable FIPS mode.
   ```
   undo fips mode enable
   ```
   By default, the FIPS mode is disabled.
3. Select the manual reboot method.

CAUTION:

System reboot might interrupt ongoing services. Please perform the previous operations with caution.

4. Configure login authentication settings.
   - If you logged in to the device through SSH, perform the following tasks without disconnecting the current user line:
     - Set the authentication mode to **scheme** for VTY lines.
     - Specify the username and password. If you do not specify the username or password, the device uses the current username and password.
   - If you logged in to the device through a console port, configure login authentication settings for the current type of user lines as described in the following table:

Current login method	Login authentication requirements
Scheme	Set the authentication to scheme and specify the username and password. If you do not specify the username or password, the device uses the current username and password.
Password	Set the authentication to password and specify the password. If you do not specify the password, the device uses the current password.
None	Set the authentication to none.

5. Save the running configuration and specify the file as the startup configuration file.
6. Delete the .mdb startup configuration file.
7. Reboot the device.

Display and maintenance commands for FIPS

Execute **display** commands in any view.

Task	Command
Display the version number of the device algorithm base.	**display crypto version**
Display the FIPS mode state.	**display fips status**

FIPS configuration examples

Example: Entering FIPS mode through automatic reboot

Network configuration

Use the automatic reboot method to enter FIPS mode, and use a console port to log in to the device in FIPS mode.

Procedure

If you want to save the current configuration, execute the **save** command before you enable FIPS mode.

Enable FIPS mode and choose the automatic reboot method to enter FIPS mode. Set the username to **root** and the password to **12345zxcvb!@#$%ZXCVB**.

```
<Sysname> system-view
[Sysname] fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
Reboot the device automatically? [Y/N]:y
The system will create a new startup configuration file for FIPS mode. After you set the login username and password for FIPS mode, the device will reboot automatically.
Enter username(1-55 characters):root
Enter password(15-63 characters):
Confirm password:
Waiting for reboot... After reboot, the device will enter FIPS mode.
```

Verifying the configuration

After the device reboots, enter a username of **root** and a password of **12345zxcvb!@#$%ZXCVB**. The system prompts you to configure a new password. After you configure the new password, the device enters FIPS mode. The new password must be different from the previous password. It must include at least 15 characters, and contain uppercase and lowercase letters, digits, and special characters. For more information about the requirements for the password, see the system output.

```
Press ENTER to get started.
login: root
Password:
First login or password reset. For security reason, you need to change your password. Please enter your password.
old password:
new password:
confirm:
Updating user information. Please wait ... ...
…
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is enabled.
```

Display the default configuration file.

```
<Sysname> more fips-startup.cfg
#
 password-control enable
#
local-user root class manage
 service-type terminal
 authorization-attribute user-role network-admin
#
 fips mode enable
#
return

<Sysname>
```

Example: Entering FIPS mode through manual reboot

Network configuration

Use the manual reboot method to enter FIPS mode, and use a console port to log in to the device in FIPS mode.

Procedure

Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

Set the number of character types a password must contain to 4, and set the minimum number of characters for each type to one character.

```
[Sysname] password-control composition type-number 4 type-length 1
```

Set the minimum length of user passwords to 15 characters.

```
[Sysname] password-control length 15
```

Add a local user account for device management, including a username of **test**, a password of **12345zxcvb!@#$%ZXCVB**, a user role of **network-admin**, and a service type of **terminal**.

```
[Sysname] local-user test class manage
[Sysname-luser-manage-test] password simple 12345zxcvb!@#$%ZXCVB
[Sysname-luser-manage-test] authorization-attribute user-role network-admin
[Sysname-luser-manage-test] service-type terminal
[Sysname-luser-manage-test] quit
```

Enable FIPS mode, and choose the manual reboot method to enter FIPS mode.

```
[Sysname] fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
Reboot the device automatically? [Y/N]:n
Change the configuration to meet FIPS mode requirements, save the configuration to the
next-startup configuration file, and then reboot to enter FIPS mode.
```

Save the current configuration to the root directory of the storage medium, and specify it as the startup configuration file.

```
[Sysname] save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait...
Saved the current configuration to mainboard device successfully.
[Sysname] quit
```

Delete the startup configuration file in binary format.

```
<Sysname> delete flash:/startup.mdb
Delete flash:/startup.mdb?[Y/N]:y
Deleting file flash:/startup.mdb...Done.
```

Reboot the device.

```
<Sysname> reboot
```

Verifying the configuration

After the device reboots, enter a username of **test** and a password of **12345zxcvb!@#$%ZXCVB**. The system prompts you to configure a new password. After you configure the new password, the

device enters FIPS mode. The new password must be different from the previous password. It must include at least 15 characters, and contain uppercase and lowercase letters, digits, and special characters. For more information about the requirements for the password, see the system output.

```
Press ENTER to get started.
login: test
Password:
First login or password reset. For security reason, you need to change your pass
word. Please enter your password.
old password:
new password:
confirm:
Updating user information. Please wait ... ...
…
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is enabled.
```

Example: Exiting FIPS mode through automatic reboot

Network configuration

After logging in to the device in FIPS mode through a console port, use the automatic reboot method to exit FIPS mode.

Procedure

Disable FIPS mode.

```
[Sysname] undo fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
The system will create a new startup configuration file for non-FIPS mode and then reboot
automatically. Continue? [Y/N]:y
Waiting for reboot... After reboot, the device will enter non-FIPS mode.
```

Verifying the configuration

After the device reboots, you can enter the system.

```
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is disabled.
```

Example: Exiting FIPS mode through manual reboot

Network configuration

After logging in to the device in FIPS mode through the console port with username **test** and password **12345zxcvb!@#$%ZXCVB**, use the manual reboot method to exit FIPS mode.

Procedure

Disable FIPS mode.

```
[Sysname] undo fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
```

```
The system will create a new startup configuration file for non-FIPS mode, and then reboot automatically. Continue? [Y/N]:n
Change the configuration to meet non-FIPS mode requirements, save the configuration to the next-startup configuration file, and then reboot to enter non-FIPS mode.
```

Save the current configuration to the root directory of the storage medium, and specify it as the startup configuration file.

```
[Sysname] save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait...
Saved the current configuration to mainboard device successfully.
[Sysname] quit
```

Delete the startup configuration file in binary format.

```
<Sysname> delete flash:/startup.mdb
Delete flash:/startup.mdb?[Y/N]:y
Deleting file flash:/startup.mdb...Done.
```

Reboot the device.

```
<Sysname> reboot
```

Verifying the configuration

After the device reboots, authentication is disabled for console login by default. You can press **Enter** to enter non-FIPS mode without authentication.

```
Press ENTER to get started.
login: test
Password:
Last successfully login time:…
…
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is disabled.
```

Specifying an SSL client policy 5
Display and maintenance commands for 802.1X client 5

Configuring an 802.1X client

About 802.1X clients

As shown in Figure 1, the 802.1X client feature allows the access device to act as the supplicant in the 802.1X architecture. For information about the 802.1X architecture, see "802.1X overview."

Figure 1 802.1X client network diagram

802.1X client tasks at a glance

To configure an 802.1X client, perform the following tasks:

1. Enabling the 802.1X client feature
2. Configuring an 802.1X client username and password
3. Specifying an 802.1X client EAP authentication method
4. (Optional.) Configuring an 802.1X client MAC address
5. (Optional.) Specifying an 802.1X client mode for sending EAP-Response and EAPOL-Logoff packets
6. (Optional.) Configuring an 802.1X client anonymous identifier
7. Specifying an SSL client policy

   This task is required when you specify PEAP-MSCHAPv2, PEAP-GTC, TTLS-MSCHAPv2, or TTLS-GTC authentication as the 802.1X client EAP authentication method.

Enabling the 802.1X client feature

1. Enter system view.

   `system-view`
2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*
3. Enable the 802.1X client feature.

   `dot1x supplicant enable`

   By default, the 802.1X client feature is disabled.

Configuring an 802.1X client username and password

Restrictions and guidelines

To ensure successful authentication, make sure the username and password configured on the 802.1X client is consistent with the username and password configured on the authentication server.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure an 802.1X client username.
   dot1x supplicant username *username*
   By default, no 802.1X client username is configured.
4. Set an 802.1X client password.
   dot1x supplicant password { **cipher** | **simple** } *string*
   By default, no 802.1X client password is configured.

Specifying an 802.1X client EAP authentication method

About this task

The following EAP authentication methods are available for the 802.1X client feature:

- MD5-Challenge.
- PEAP-MSCHAPv2.
- PEAP-GTC.
- TTLS-MSCHAPv2.
- TTLS-GTC.

Restrictions and guidelines

The following matrix shows the restrictions for the selection of authentication methods on the 802.1X client and the authenticator:

Authentication method specified on the 802.1X client	Packet exchange method specified on the authenticator
MD5-Challenge	• CHAP • EAP
• PEAP-MSCHAPv2 • PEAP-GTC • TTLS-MSCHAPv2 • TTLS-GTC	EAP

For information about 802.1X packet exchange methods, see "Configuring 802.1X."

Make sure the specified 802.1X client EAP authentication method is supported by the authentication server.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Specify an 802.1X client EAP authentication method.

   dot1x supplicant eap-method { **md5** | **peap-gtc** | **peap-mschapv2** | **ttls-gtc** | **ttls-mschapv2** }

   By default, the EAP authentication method is MD5-Challenge.

Configuring an 802.1X client MAC address

About this task

The authenticator adds the MAC address of an authenticated 802.1X client to the MAC address table and then assigns access rights to the client.

If the device has multiple Ethernet interfaces that act as 802.1X clients to seek MACsec protection, configure a unique MAC address for each interface to ensure successful 802.1X client authentication. For information about MACsec, see "Configuring MACsec."

You can use either of the following methods to configure a unique MAC address for each interface:

- Execute the **mac-address** command in Ethernet interface view. For information about this command, see *Layer 2—LAN Switching Command Reference*.
- Configure an 802.1X client MAC address.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Configure an 802.1X client MAC address.

   dot1x supplicant mac-address *mac-address*

   By default, an Ethernet interface uses the interface's MAC address for 802.1X client authentication. If the interface's MAC address is unavailable, the interface uses the device's MAC address for 802.1X client authentication.

Specifying an 802.1X client mode for sending EAP-Response and EAPOL-Logoff packets

About this task

802.1X client authentication supports unicast and multicast modes to send EAP-Response and EAPOL-Logoff packets. As a best practice, use multicast mode to avoid 802.1X client authentication failures if the NAS device in the network does not support receiving unicast EAP-Response or EAPOL-Logoff packets.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Specify a mode for 802.1X client authentication to send EAP-Response and EAPOL-Logoff packets.
   dot1x supplicant transmit-mode { **multicast** | **unicast** }
   By default, 802.1X client authentication uses unicast mode to send EAP-Response and EAPOL-Logoff packets.

Configuring an 802.1X client anonymous identifier

About this task

At the first authentication phase, packets sent to the authenticator are not encrypted. The use of an 802.1X client anonymous identifier prevents the 802.1X client username from being disclosed at the first phase. The 802.1X client sends the anonymous identifier to the authenticator instead of the 802.1X client username. The 802.1X client username will be sent to the authenticator in encrypted packets at the second phase.

If no 802.1X client anonymous identifier is configured, the 802.1X client sends the 802.1X client username at the first authentication phase.

The configured 802.1X client anonymous identifier takes effect only if one of the following EAP authentication methods is used:

- PEAP-MSCHAPv2.
- PEAP-GTC.
- TTLS-MSCHAPv2.
- TTLS-GTC.

If the MD5-Challenge EAP authentication is used, the configured 802.1X client anonymous identifier does not take effect. The 802.1X client uses the 802.1X client username at the first authentication phase.

Restrictions and guidelines

Do not configure the 802.1X client anonymous identifier if the vendor-specific authentication server cannot identify anonymous identifiers.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure an 802.1X client anonymous identifier.
   dot1x supplicant anonymous identify *identifier*
   By default, no 802.1X client anonymous identifier is configured.

Specifying an SSL client policy

About this task

If the PEAP-MSCHAPv2, PEAP-GTC, TTLS-MSCHAPv2, or TTLS-GTC authentication is used, the 802.1X client authentication process is as follows:

- **The first phase**—The 802.1X client acts as an SSL client to negotiate with the SSL server.

  The SSL client uses the SSL parameters defined in the specified SSL client policy to establish a connection with the SSL server for negotiation. The SSL parameters include a PKI domain, supported cipher suites, and the SSL version. For information about SSL client policy configuration, see "Configuring SSL."
- **The second phase**—The 802.1X client uses the negotiated result to encrypt and transmit the interchanged authentication packets.

If the MD5-Challenge authentication is used, the 802.1X client does not use an SSL client policy during the authentication process.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

   interface *interface-type interface-number*
3. Specify an SSL client policy.

   dot1x supplicant ssl-client-policy *policy-name*

   By default, the default SSL client policy is used.

Display and maintenance commands for 802.1X client

Execute **display** commands in any view.

Task	Command
Display 802.1X client information.	**display dot1x supplicant** [**interface** *interface-type interface-number*]

Configuring attack detection and prevention

Overview

Attack detection and prevention enables a device to detect attacks by inspecting arriving packets, and to take prevention actions (such as packet dropping) to protect a private network.

Attacks that the device can prevent

This section describes the attacks that the device can detect and prevent.

TCP fragment attack

An attacker launches TCP fragment attacks by sending attack TCP fragments defined in RFC 1858:

- First fragments in which the TCP header is smaller than 20 bytes.
- Non-first fragments with a fragment offset of 8 bytes (FO=1).

Typically, packet filter detects the source and destination IP addresses, source and destination ports, and transport layer protocol of the first fragment of a TCP packet. If the first fragment passes the detection, all subsequent fragments of the TCP packet are allowed to pass through.

Because the first fragment of attack TCP packets does not hit any match in the packet filter, the subsequent fragments can all pass through. After the receiving host reassembles the fragments, a TCP fragment attack occurs.

To prevent TCP fragment attacks, enable TCP fragment attack prevention to drop attack TCP fragments.

Login dictionary attack

The login dictionary attack is an automated process to attempt to log in by trying all possible passwords from a pre-arranged list of values (the dictionary). Multiple login attempts can occur in a short period of time.

You can configure the login delay feature to slow down the login dictionary attacks. This feature enables the device to delay accepting another login request after detecting a failed login attempt for a user.

Configuring TCP fragment attack prevention

The TCP fragment attack prevention feature detects the length and fragment offset of received TCP fragments and drops attack TCP fragments. The device supports verifying only TCP fragments forwarded through the CPU.

To configure TCP fragment attack prevention:

1. Enter system view.
   ```
   system-view
   ```
2. Enable TCP fragment attack prevention.
   ```
   attack-defense tcp fragment enable
   ```

By default, TCP fragment attack prevention is enabled.

Enabling the login delay

The login delay feature delays the device from accepting a login request from a user after the user fails a login attempt. This feature can slow down login dictionary attacks.

To enable the login delay:

1. Enter system view.

   system-view

2. Enable the login delay feature.

   attack-defense login reauthentication-delay *seconds*

   By default, the login delay feature is disabled. The device does not delay accepting a login request from a user who has failed a login attempt.

All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes the high availability fundamentals and configuration procedures. The high availability technologies include fault detection and fault failover. Failure detection technologies focus on fault detection and isolation. Failover technologies focus on network recovery.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators working with the S5170-EI switch series.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** >

	Folder.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring Ethernet OAM

About Ethernet OAM

Ethernet Operation, Administration, and Maintenance (OAM) is a tool that monitors Layer 2 link status and addresses common link-related issues on the "last mile." Ethernet OAM improves Ethernet management and maintainability. You can use it to monitor the status of the point-to-point link between two directly connected devices.

Major functions of Ethernet OAM

Ethernet OAM provides the following functions:

- **Link performance monitoring**—Monitors the performance indices of a link, including packet loss, delay, and jitter, and collects traffic statistics of various types.
- **Fault detection and alarm**—Checks the connectivity of a link by sending OAM protocol data units (OAMPDUs) and reports to the network administrators when a link error occurs.
- **Remote loopback**—Checks link quality and locates link errors by looping back OAMPDUs.

Ethernet OAMPDUs

Ethernet OAM operates on the data link layer. Ethernet OAM reports the link status by periodically exchanging OAMPDUs between devices, so that the administrator can effectively manage the network.

Ethernet OAMPDUs include the following types shown in Table 1.

Table 1 Functions of different types of OAMPDUs

OAMPDU type	Function
Information OAMPDU	Used for transmitting state information of an Ethernet OAM entity, including the information about the local device and remote devices, and customized information, to the remote Ethernet OAM entity, and maintaining OAM connections.
Event Notification OAMPDU	Used by link monitoring to notify the remote OAM entity when it detects problems on the link in between.
Loopback Control OAMPDU	Used for remote loopback control. By inserting the information used to enable/disable loopback to a loopback control OAMPDU, you can enable/disable loopback on a remote OAM entity.

NOTE:

Throughout this document, an Ethernet OAM-enabled port is called an Ethernet OAM entity or an OAM entity.

How Ethernet OAM works

This section describes the working procedures of Ethernet OAM.

Ethernet OAM connection establishment

OAM connection establishment is also known as the Discovery phase, where an Ethernet OAM entity discovers the remote OAM entity to establish a session.

In this phase, two connected OAM entities exchange Information OAMPDUs to advertise their OAM configuration and capabilities to each other for a comparison. If their Loopback, link detection, and link event settings match, the OAM entities establish an OAM connection.

An OAM entity operates in active mode or passive mode. OAM entities in active mode initiate OAM connections, and OAM entities in passive mode wait and respond to the OAM connection requests. To set up an OAM connection between two OAM entities, you must set at least one entity to operate in active mode.

Table 2 shows the actions that a device can perform in different modes.

Table 2 Active Ethernet OAM mode and passive Ethernet OAM mode

Item	Active Ethernet OAM mode	Passive Ethernet OAM mode
Initiating OAM Discovery	Available	Unavailable
Responding to OAM Discovery	Available	Available
Transmitting Information OAMPDUs	Available	Available
Transmitting Event Notification OAMPDUs	Available	Available
Transmitting Information OAMPDUs without any TLV	Available	Available
Transmitting Loopback Control OAMPDUs	Available	Unavailable
Responding to Loopback Control OAMPDUs	Available	Available

After an Ethernet OAM connection is established, the Ethernet OAM entities exchange Information OAMPDUs at the handshake packet transmission interval to detect the availability of the Ethernet OAM connection. If an Ethernet OAM entity receives no Information OAMPDU within the Ethernet OAM connection timeout time, the Ethernet OAM connection is considered disconnected.

Link monitoring

Error detection in an Ethernet is difficult, especially when the physical connection in the network is not disconnected, but network performance is degrading gradually.

Link monitoring detects link faults in various environments. Ethernet OAM entities monitor link status by exchanging Event Notification OAMPDUs. When detecting one of the link error events listed in Table 3, an OAM entity sends an Event Notification OAMPDU to its peer OAM entity. The network administrator can keep track of network status changes by retrieving the log.

Table 3 Ethernet OAM link error events

Ethernet OAM link events	Description
Errored symbol event	An errored symbol event occurs when the number of detected symbol errors in the detection window (specified number of received symbols) exceeds the predefined threshold.
Errored frame event	An errored frame event occurs when the number of detected error frames in the detection window (specified detection interval) exceeds the predefined threshold.
Errored frame period event	An errored frame period event occurs when the number of frame errors in the detection window (specified number of received frames) exceeds the predefined threshold.
Errored frame seconds event	An errored frame seconds event occurs when the number of errored frame seconds (the second in which an errored frame appears is called an

Ethernet OAM link events	Description
	errored frame second) detected on a port in the detection window (specified detection interval) reaches the predefined threshold.

Remote fault detection

Information OAMPDUs are exchanged periodically among Ethernet OAM entities across established OAM connections. When traffic is interrupted due to device failure or unavailability, the Ethernet OAM entity at the faulty end sends error information to its peer. The Ethernet OAM entity uses the flag field in Information OAMPDUs to indicate the error information (any critical link event type as shown in Table 4). You can use the log information to track ongoing link status and troubleshoot problems promptly.

Table 4 Critical link events

Type	Description	OAMPDU transmission frequencies
Link Fault	Peer link signal is lost.	Once per second.
Dying Gasp	An unexpected fault, such as power failure, occurred.	Non-stop.
Critical Event	An undetermined critical event happened.	Non-stop.

Remote loopback

Remote loopback is available only after the Ethernet OAM connection is established. With remote loopback enabled, the Ethernet OAM entity in active mode sends non-OAMPDUs to its peer. After receiving these frames, the peer does not forward them according to their destination addresses. Instead, it returns them to the sender along the original path.

Remote loopback enables you to check the link status and locate link failures. Performing remote loopback periodically helps to detect network faults promptly. Furthermore, performing remote loopback by network segments helps to locate network faults.

Protocols and standards

IEEE 802.3ah, *Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications*

Restrictions and guidelines: Ethernet OAM configuration

The device's support for sending and receiving Information OAMPDUs carrying critical link events is as follows:

- Can receive Information OAMPDUs carrying the critical link events listed in Table 4.
- Cannot send Information OAMPDUs carrying Link Fault events.
- Can send Information OAMPDUs carrying Dying Gasp events when the device is rebooted or relevant ports are manually shut down. Physical IRF ports, however, are unable to send this type of OAMPDUs.
- Cannot send Information OAMPDUs carrying Critical Events.

Ethernet OAM tasks at a glance

To configure Ethernet OAM, perform the following tasks:

1. Configuring basic Ethernet OAM functions
2. (Optional.) Configuring the Ethernet OAM connection detection timers
3. (Optional.) Configuring link event detection
   - Configuring errored symbol event detection
   - Configuring errored frame event detection
   - Configuring errored frame period event detection
   - Configuring errored frame seconds event detection
4. (Optional.) Configuring the action a port takes after it receives an Ethernet OAM event from the remote end
5. (Optional.) Configuring Ethernet OAM remote loopback
   - Enabling Ethernet OAM remote loopback for a port
   - Rejecting the Ethernet OAM remote loopback request from a remote port

Configuring basic Ethernet OAM functions

About this task

To set up an Ethernet OAM connection between two Ethernet OAM entities, you must set at least one entity to operate in active mode. An Ethernet OAM entity can initiate OAM connection only in active mode.

Restrictions and guidelines

To change the Ethernet OAM mode on an Ethernet OAM-enabled port, first disable Ethernet OAM on the port.

Procedure

1. Enter system view.

   System-view
2. Enter Layer 2 Ethernet port view.

   interface *interface-type interface-number*
3. Set the Ethernet OAM mode.

   oam mode { **active** | **passive** }

   The default is active Ethernet OAM mode.
4. Enable Ethernet OAM.

   oam enable

   Ethernet OAM is disabled by default.

Configuring the Ethernet OAM connection detection timers

About the Ethernet OAM connection detection timers

After an Ethernet OAM connection is established, the Ethernet OAM entities exchange Information OAMPDUs at the handshake packet transmission interval to detect the availability of the Ethernet OAM connection. If an Ethernet OAM entity receives no Information OAMPDU within the Ethernet OAM connection timeout time, the Ethernet OAM connection is considered disconnected.

By adjusting the handshake packet transmission interval and the connection timeout timer, you can change the detection time resolution for Ethernet OAM connections.

Restrictions and guidelines for configuring Ethernet OAM connection detection timers

When you configure Ethernet OAM, follow these restrictions and guidelines:

- You can configure this command in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.
- After the timeout timer of an Ethernet OAM connection expires, the local OAM entity ages out and terminates its connection with the peer OAM entity. To keep the Ethernet OAM connections stable, set the connection timeout timer to be at least five times the handshake packet transmission interval.

Configuring the Ethernet OAM connection detection timers globally

1. Enter system view.
   System-view
2. Configure the Ethernet OAM handshake packet transmission interval.
   oam global timer hello *interval*
   The default is 1000 milliseconds.
3. Configure the Ethernet OAM connection timeout timer.
   oam global timer keepalive *interval*
   The default is 5000 milliseconds.

Configuring the Ethernet OAM connection detection timers on a port

1. Enter system view.
   System-view
2. Enter Layer 2 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the Ethernet OAM handshake packet transmission interval.
   oam timer hello *interval*

By default, an interface uses the value configured globally.

4. Configure the Ethernet OAM connection timeout timer.
   oam timer keepalive *interval*
   By default, an interface uses the value configured globally.

Configuring errored symbol event detection

Restrictions and guidelines for configuring errored symbol event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored symbol event detection globally

1. Enter system view.
   system-view
2. Configure the errored symbol event detection window.
   oam global errored-symbol-period window *window-value*
   By default, the errored symbol event detection window is 100000000.
3. Configure the errored symbol event triggering threshold.
   oam global errored-symbol-period threshold *threshold-value*
   By default, the errored symbol event triggering threshold is 1.

Configuring errored symbol event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored symbol event detection window.
   oam errored-symbol-period window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored symbol event triggering threshold.
   oam errored-symbol-period threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring errored frame event detection

Restrictions and guidelines for configuring errored frame event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored frame event detection globally

1. Enter system view.
   system-view
2. Configure the errored frame event detection window.
   oam global errored-frame window *window-value*
   By default, the errored frame event detection window is 1000 milliseconds.
3. Configure the errored frame event triggering threshold.
   oam global errored-frame threshold *threshold-value*
   By default, the errored frame event triggering threshold is 1.

Configuring errored frame event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame event detection window.
   oam errored-frame window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame event triggering threshold.
   oam errored-frame threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring errored frame period event detection

Restrictions and guidelines for configuring errored frame period event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored frame period event detection globally

1. Enter system view.

system-view

2. Configure the errored frame period event detection window.
   oam global errored-frame-period window *window-value*
   By default, the errored frame period event detection window is 10000000.
3. Configure the errored frame period event triggering threshold.
   oam global errored-frame-period threshold *threshold-value*
   By default, the errored frame period event triggering threshold is 1.

Configuring errored frame period event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame period event detection window.
   oam errored-frame-period window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame period event triggering threshold.
   oam errored-frame-period threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring errored frame seconds event detection

Restrictions and guidelines for configuring errored frame seconds event detection

- You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.
- Make sure the errored frame seconds triggering threshold is less than the errored frame seconds detection window. Otherwise, no errored frame seconds event can be generated.

Configuring errored frame seconds event detection globally

1. Enter system view.
   system-view
2. Configure the errored frame seconds event detection window.
   oam global errored-frame-seconds window *window-value*
   By default, the errored frame seconds event detection window is 60000 milliseconds.
3. Configure the errored frame seconds event triggering threshold.
   oam global errored-frame-seconds threshold *threshold-value*
   By default, the errored frame seconds event triggering threshold is 1.

Configuring errored frame seconds event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame seconds event detection window.
   oam errored-frame-seconds window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame seconds event triggering threshold.
   oam errored-frame-seconds threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring the action a port takes after it receives an Ethernet OAM event from the remote end

About this task

This feature enables a port to log events and automatically terminate the OAM connection and set the link state to down.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the action the port takes after it receives an Ethernet OAM event from the remote end.
   oam remote-failure { **connection-expired** | **critical-event** | **dying-gasp** | **link-fault** } **action error-link-down**
   By default, the port only logs the Ethernet OAM event it receives from the remote end.

Enabling Ethernet OAM remote loopback for a port

△ **CAUTION:**
Use this feature with caution, because enabling Ethernet OAM remote loopback impacts other services.

About Ethernet OAM remote loopback

When you enable Ethernet OAM remote loopback on a port, the port sends Loopback Control OAMPDUs to a remote port. After receiving the Loopback Control OAMPDUs, the remote port enters the loopback state. The remote port then returns any packets sent from the local port except

OAMPDUs. By observing how many of these packets return, you can calculate the packet loss ratio on the link and evaluate the link performance.

Restrictions and guidelines for enabling Ethernet OAM remote loopback

- Ethernet OAM remote loopback is available only after the Ethernet OAM connection is established. It can be performed only by Ethernet OAM entities operating in active Ethernet OAM mode.
- Remote loopback is available only on full-duplex links that support remote loopback at both ends.
- Ethernet OAM remote loopback must be supported by both the remote port and the sending port.
- Enabling Ethernet OAM remote loopback interrupts data communications. After Ethernet OAM remote loopback is disabled, all the ports involved will go down and then come up. Ethernet OAM remote loopback can be disabled by any of the following events:
  - Disabling Ethernet OAM.
  - Disabling Ethernet OAM remote loopback.
  - Timeout of the Ethernet OAM connection.
- Enabling internal loopback test on a port in remote loopback test can terminate the remote loopback test. For more information about loopback test, see *Interface Configuration Guide*.
- You can enable Ethernet OAM remote loopback on a specific port in user view, system view, or Ethernet port view. The configuration effects are the same.

Enabling Ethernet OAM remote loopback for a port in system view

1. (Optional.) Enter system view.
   `system-view`
   You can also perform this task in user view.
2. Enable Ethernet OAM remote loopback for a port.
   `oam remote-loopback start interface` *`interface-type interface-number`*
   By default, Ethernet OAM remote loopback is disabled.

Enabling Ethernet OAM remote loopback for a port in interface view

1. Enter system view.
   `system-view`
2. Enter Layer 2 Ethernet port view.
   `interface` *`interface-type interface-number`*
3. Enable Ethernet OAM remote loopback on the port.
   `oam remote-loopback start`
   By default, Ethernet OAM remote loopback is disabled.

Rejecting the Ethernet OAM remote loopback request from a remote port

About this task

The Ethernet OAM remote loopback feature impacts other services. To solve this problem, you can disable a port from being controlled by the Loopback Control OAMPDUs sent by a remote port. The local port then rejects the Ethernet OAM remote loopback request from the remote port.

Restrictions and guidelines

This feature does not affect the ongoing remote loopback test on the port. It takes effect when the next remote loopback starts on the port.

Procedure

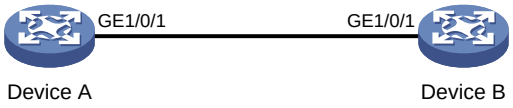
1. Enter system view.
   `system-view`
2. Enter Layer 2 Ethernet port view.
   `interface` *`interface-type interface-number`*
3. Reject the Ethernet OAM remote loopback request from a remote port.
   `oam remote-loopback reject-request`
   By default, a port does not reject the Ethernet OAM remote loopback request from a remote port.

Display and maintenance commands for Ethernet OAM

Execute **`display`** commands in any view and **`reset`** commands in user view:

Task	Command
Display information about an Ethernet OAM connection.	**`display oam`** { **`local`** | **`remote`** } [**`interface`** *`interface-type interface-number`*]
Display Ethernet OAM configuration.	**`display oam configuration`** [**`interface`** *`interface-type interface-number`*]
Display the statistics on critical events after an Ethernet OAM connection is established.	**`display oam critical-event`** [**`interface`** *`interface-type interface-number`*]
Display the statistics on Ethernet OAM link error events after an Ethernet OAM connection is established.	**`display oam link-event`** { **`local`** | **`remote`** } [**`interface`** *`interface-type interface-number`*]
Clear statistics on Ethernet OAM packets and Ethernet OAM link error events.	**`reset oam`** [**`interface`** *`interface-type interface-number`*]

Ethernet OAM configuration examples



Example: Configuring Ethernet OAM

Network configuration

On the network shown in Figure 1, perform the following operations:

- Enable Ethernet OAM on Device A and Device B to auto-detect link errors between the two devices
- Determine the performance of the link between Device A and Device B by collecting statistics about the error frames received by Device A

Figure 1 Network diagram

Procedure

1. Configure Device A:

   # Configure GigabitEthernet 1/0/1 to operate in active Ethernet OAM mode, and enable Ethernet OAM for it.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] oam mode active
   [DeviceA-GigabitEthernet1/0/1] oam enable
   ```

   # Set the errored frame event detection window to 20000 milliseconds, and set the errored frame event triggering threshold to 10.

   ```
   [DeviceA-GigabitEthernet1/0/1] oam errored-frame window 200
   [DeviceA-GigabitEthernet1/0/1] oam errored-frame threshold 10
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

2. Configure Device B:

   # Configure GigabitEthernet 1/0/1 to operate in passive Ethernet OAM mode (the default), and enable Ethernet OAM for it.

   ```
   <DeviceB> system-view
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] oam mode passive
   [DeviceB-GigabitEthernet1/0/1] oam enable
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Use the **`display oam critical-event`** command to display the statistics of Ethernet OAM critical link events. For example:

Display the statistics of Ethernet OAM critical link events on all the ports of Device A.

```
[DeviceA] display oam critical-event
-----------[GigabitEthernet1/0/1] -----------
 Local link status   : UP
 Event statistics
   Link fault        : Not occurred
```

```
   Dying gasp        : Not occurred
   Critical event    : Not occurred
```

The output shows that no critical link event occurred on the link between Device A and Device B.

Use the **display oam link-event** command to display the statistics of Ethernet OAM link events. For example:

Display Ethernet OAM link event statistics of the local end of Device A.

```
[DeviceA] display oam link-event local
------------ [GigabitEthernet1/0/1] -----------
 Link status: UP
 OAM local errored frame event
   Event time stamp        : 5789 x 100 milliseconds
   Errored frame window    : 200 x 100 milliseconds
   Errored frame threshold : 10 error frames
   Errored frame           : 13 error frames
   Error running total     : 350 error frames
   Event running total     : 17 events
```

The output shows the following:

- 350 errors occurred after Ethernet OAM is enabled on Device A.
- 17 errors were caused by error frames.
- The link is unstable.

Configuring CFD

About CFD

Connectivity Fault Detection (CFD), which conforms to IEEE 802.1ag Connectivity Fault Management (CFM) and ITU-T Y.1731, is an end-to-end per-VLAN link layer OAM mechanism. CFD is used for link connectivity detection, fault verification, and fault location.

Basic CFD concepts

Maintenance domain

A maintenance domain (MD) defines the network or part of the network where CFD plays its role. An MD is identified by its MD name.

Maintenance association

A maintenance association (MA) is a part of an MD. You can configure multiple MAs in an MD as needed. An MA is identified by the MD name + MA name.

An MA serves the specified VLAN or no VLAN. An MA that serves a VLAN is considered to be carrying VLAN attribute. An MA that serves no VLAN is considered to be carrying no VLAN attribute.

Maintenance point

An MP is configured on a port and belongs to an MA. MPs include the following types: maintenance association end points (MEPs) and maintenance association intermediate points (MIPs).

MEPs define the boundary of the MA. Each MEP is identified by a MEP ID.

MEPs include inward-facing MEPs and outward-facing MEPs:

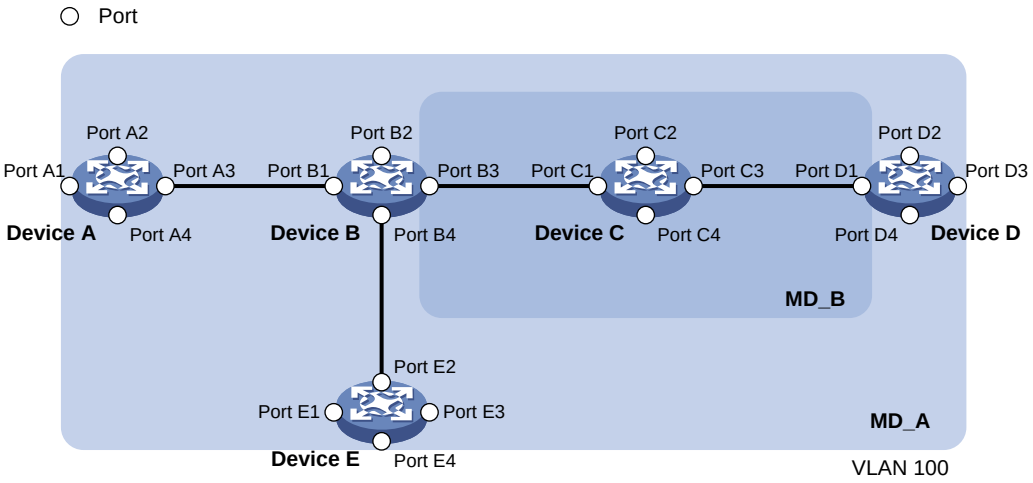
- An outward-facing MEP sends packets to its host port.
- An inward-facing MEP does not send packets to its host port. Rather, it sends packets to other ports on the device.

A MIP is internal to an MA. It cannot send CFD packets actively, but it can handle and respond to CFD packets. MIPs are automatically created by the device. By cooperating with MEPs, a MIP can perform a function similar to ping and traceroute.

MEP list

A MEP list is a collection of local MEPs allowed to be configured and the remote MEPs to be monitored in the same MA. It lists all the MEPs configured on different devices in the same MA. The MEPs all have unique MEP IDs. When a MEP receives from a remote device a continuity check message (CCM) carrying a MEP ID not in the MEP list of the MA, it drops the message.

The local device must send CCM messages carrying the Remote Defect Indication (RDI) flag bits. Otherwise, the peer device cannot sense certain failures. When a local MEP has not learned all remote MEPs in the MEP list, the MEPs in the MA might not carry the RDI flag bits in CCMs.



CFD levels

MD levels

To accurately locate faults, CFD introduces eight levels (from 0 to 7) to MDs. The bigger the number, the higher the level and the larger the area covered. Domains can touch or nest (if the outer domain has a higher level than the nested one) but cannot intersect or overlap.

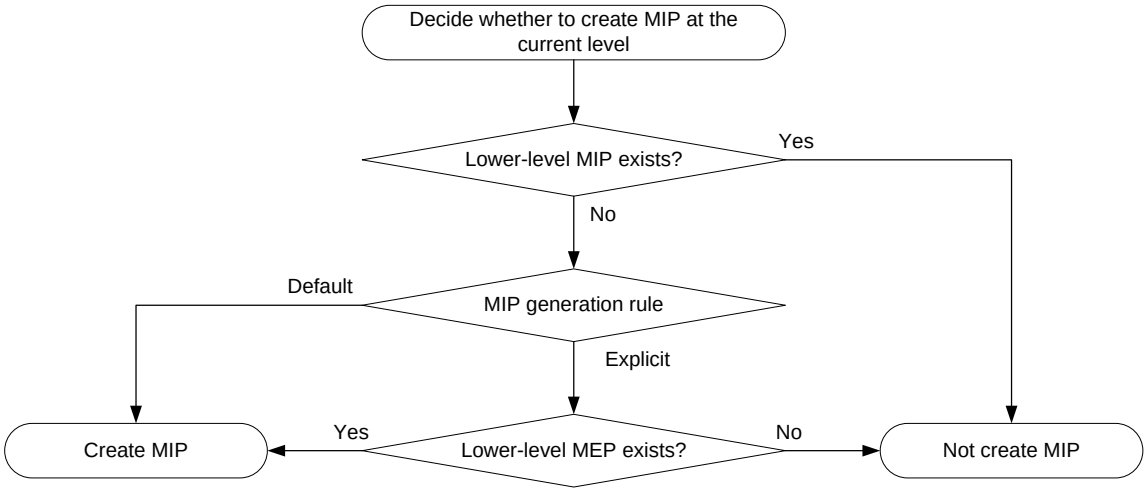
MD levels facilitate fault location and make fault location more accurate. As shown in Figure 1, MD_A in light blue nests MD_B in dark blue. If a connectivity fault is detected at the boundary of MD_A, any of the devices in MD_A, including Device A through Device E, might fail. If a connectivity fault is also detected at the boundary of MD_B, the failure points can be any of Device B through Device D. If the devices in MD_B can operate correctly, at least Device C is operational.

Figure 1 Two nested MDs

CFD exchanges messages and performs operations on a per-domain basis. By planning MDs correctly in a network, you can use CFD to rapidly locate failure points.

MA and MP levels

The level of an MA equals the level of the MD to which the MA belongs.



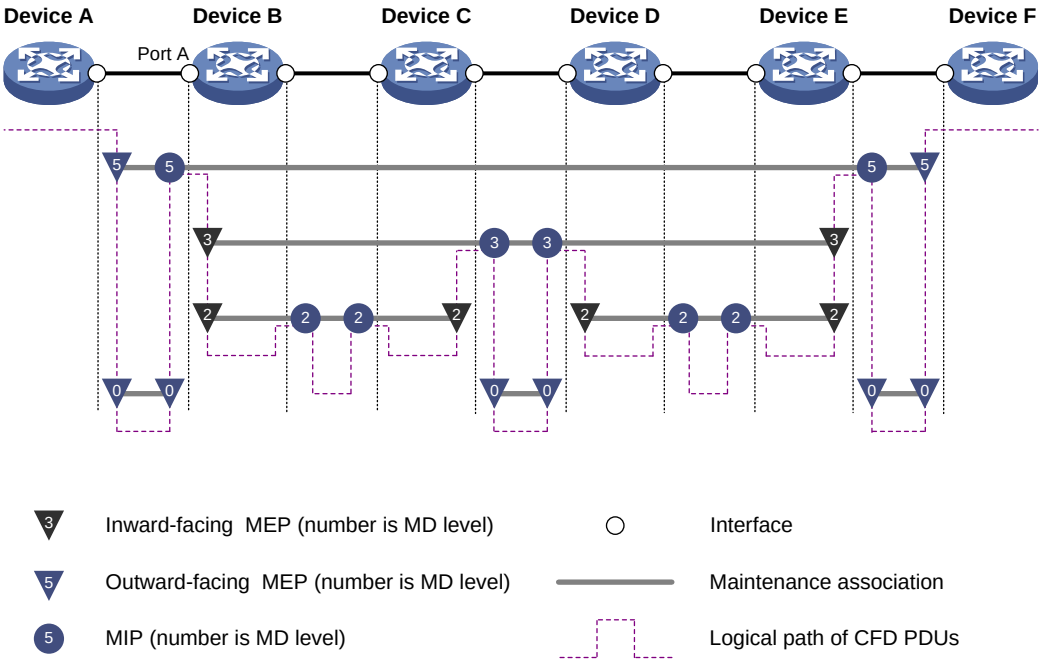
The level of a MEP equals the level of the MD to which the MEP belongs.

The level of a MIP is defined by its generation rule and the MD to which the MIP belongs. MIPs are generated on each port automatically according to the following MIP generation rules:

- **Default rule**—If no lower-level MIP exists on an interface, a MIP is created on the current level. A MIP can be created even if no MEP is configured on the interface.
- **Explicit rule**—If no lower-level MIP exists and a lower-level MEP exists on an interface, a MIP is created on the current level. A MIP can be created only when a lower-level MEP is created on the interface.

If a port has no MIP, the system will check the MAs in each MD (from low to high levels), and follow the procedure as described in Figure 2 to create or not to create MIPs at the current level.

Figure 2 Procedure of creating MIPs



CFD grading example

Figure 3 demonstrates a grading example of the CFD module. Four levels of MDs (0, 2, 3, and 5) are designed. The bigger the number, the higher the level and the larger the area covered. MPs are configured on the ports of Device A through Device F. Port A of Device B is configured with the following MPs:

- A level 5 MIP.
- A level 3 inward-facing MEP.
- A level 2 inward-facing MEP.
- A level 0 outward-facing MEP.

Figure 3 CFD grading example

Packet processing of MPs

For an MA carrying VLAN attribute, MPs of the MA send packets only in the VLAN that the MA serves. The level of packets sent by an MP equals the level of the MD to which the MP belongs.

For an MA not carrying VLAN attribute, MPs of the MA can only be outward-facing MEPs. The level of packets sent by an outward-facing MEP equals the level of the MD to which the MEP belongs.

A MEP forwards packets at a higher level without any processing and only processes packets of its level or lower.

A MIP forwards packets of a different level without any processing and only processes packets of its level.

CFD functions

CFD functions, which are implemented through the MPs, include:

- Continuity check (CC).
- Loopback (LB).
- Linktrace (LT).
- Alarm indication signal (AIS).
- Loss measurement (LM).
- Delay measurement (DM).
- Test (TST).

Continuity check

Connectivity faults are usually caused by device faults or configuration errors. Continuity check examines the connectivity between MEPs. This function is implemented through periodic sending of CCMs by the MEPs. A CCM sent by one MEP is intended to be received by all the other MEPs in the same MA. If a MEP fails to receive the CCMs within 3.5 times the sending interval, the link is considered as faulty and a log is generated. When multiple MEPs send CCMs at the same time, the multipoint-to-multipoint link check is achieved. CCM frames are multicast frames.

Loopback

Similar to ping at the IP layer, loopback verifies the connectivity between a source device and a target device. To implement this function, the source MEP sends loopback messages (LBMs) to the target MEP. Depending on whether the source MEP can receive a loopback reply message (LBR) from the target MEP, the link state between the two can be verified.

LBM frames are multicast and unicast frames. The device can send and receive unicast LBM frames, and can receive multicast LBM frames but cannot send multicast LBM frames. LBR frames are unicast frames.

Linktrace

Linktrace is similar to traceroute. It identifies the path between the source MEP and the target MP. The source MEP sends the linktrace messages (LTMs) to the target MP. After receiving the messages, the target MP and the MIPs that the LTM frames pass send back linktrace reply messages (LTRs) to the source MEP. Based on the reply messages, the source MEP can identify the path to the target MP. LTM frames are multicast frames and LTRs are unicast frames.

AIS

The AIS function suppresses the number of error alarms reported by MEPs. If a local MEP does not receive any CCM frames from its peer MEP within 3.5 times the CCM transmission interval, it immediately starts sending AIS frames. The AIS frames are sent periodically in the opposite direction of CCM frames. When the peer MEP receives the AIS frames, it suppresses the error alarms locally, and continues to send the AIS frames. If the local MEP receives CCM frames within 3.5 times the

CCM transmission interval, it stops sending AIS frames and restores the error alarm function. AIS frames are multicast frames.

LM

The LM function measures the frame loss in a certain direction between a pair of MEPs. The source MEP sends loss measurement messages (LMMs) to the target MEP. The target MEP responds with loss measurement replies (LMRs). The source MEP calculates the number of lost frames according to the counter values of the two consecutive LMRs (the current LMR and the previous LMR). LMMs and LMRs are unicast frames.

DM

The DM function measures frame delays between two MEPs, including the following types:

- One-way frame delay measurement

  The source MEP sends a one-way delay measurement (1DM) frame, which carries the transmission time, to the target MEP. When the target MEP receives the 1DM frame, it does the following:

  - Records the reception time.
  - Calculates and records the link transmission delay and jitter (delay variation) according to the transmission time and reception time.

  1DM frames are unicast frames.

- Two-way frame delay measurement

  The source MEP sends a delay measurement message (DMM), which carries the transmission time, to the target MEP. When the target MEP receives the DMM, it responds with a delay measurement reply (DMR). The DMR carries the reception time and transmission time of the DMM and the transmission time of the DMR. When the source MEP receives the DMR, it does the following:

  - Records the DMR reception time.
  - Calculates the link transmission delay and jitter according to the DMR reception time and DMM transmission time.

  DMM frames and DMR frames are unicast frames.

TST

The TST function tests the bit errors between two MEPs. The source MEP sends a TST frame, which carries the test pattern, such as pseudo random bit sequence (PRBS) or all-zero, to the target MEP. When the target MEP receives the TST frame, it determines the bit errors by calculating and comparing the content of the TST frame. TST frames are unicast frames.

EAIS

Ethernet Alarm Indication Signal (EAIS) enables collaboration between the Ethernet port status and the AIS function. When a port on the device (not necessarily an MP) goes down, it immediately starts to send EAIS frames periodically to suppress the error alarms. When the port goes up again, it immediately stops sending EAIS frames. When the MEP receives the EAIS frames, it suppresses the error alarms locally, and continues to send the EAIS frames. If a MEP receives no EAIS frames within 3.5 times the EAIS frame transmission interval, the fault is considered cleared. The port stops sending EAIS frames and restores the error alarm function. EAIS frames are multicast frames.

Collaboration between CFD and Track

CFD can collaborate with Track as follows:

- If CFD detects that the peer is reachable, it notifies the Track module. The Track module sets the state of the track entry to Positive.

- If CFD detects that the peer is unreachable, it notifies the Track module. The Track module sets the state of the track entry to Negative.

For more information about Track, see "Configuring Track."

Protocols and standards

- IEEE 802.1ag, *Virtual Bridged Local Area Networks Amendment 5: Connectivity Fault Management*
- ITU-T Y.1731, *OAM functions and mechanisms for Ethernet based networks*

Restrictions and guidelines: CFD configuration

When you configure CFD, follow these restrictions and guidelines:

- Configure CC before you use the MEP ID of the remote MEP to configure other CFD functions. This restriction does not apply when you use the MAC address of the remote MEP to configure other CFD functions.
- Typically, a port blocked by the spanning tree feature cannot receive or send CFD messages except in the following cases:
  - The port is configured as an outward-facing MEP.
  - The port is configured as a MIP or inward-facing MEP, which can still receive and send CFD messages except CCM messages.

  For more information about the spanning tree feature, see *Layer 2—LAN Switching Configuration Guide*.

CFD tasks at a glance

To configure CFD, perform the following tasks:

1. Configuring basic CFD settings
   a. Enabling CFD
   b. Configuring service instances
   c. Configuring MEPs
   d. Configuring MIP auto-generation rules
2. Configuring CFD functions
   a. Configuring CC
   b. (Optional.) Configuring LB
   c. (Optional.) Configuring LT
   d. (Optional.) Configuring AIS
   e. (Optional.) Configuring LM
   f. (Optional.) Configuring one-way DM
   g. (Optional.) Configuring two-way DM
   h. (Optional.) Configuring TST
3. (Optional.) Configuring EAIS
4. Enabling CC status change notification

Prerequisites for CFD

For CFD to work correctly, design the network by performing the following tasks:

- Grade the MDs in the entire network, and define the boundary of each MD.
- Assign a name for each MD. Make sure the devices in the same MD use the same MD name.
- Define the MA in each MD according to the VLAN you want to monitor.
- Assign a name for each MA. Make sure that the devices in the same MA in the same MD use the same MA name.
- Determine the MEP list of each MA in each MD. Make sure devices in the same MA maintain the same MEP list.
- At the edges of MD and MA, MEPs must be designed at the device port. MIPs can be designed on devices or ports that are not at the edges.

Configuring basic CFD settings

Enabling CFD

1. Enter system view.

   system-view
2. Enable CFD.

   cfd enable

   By default, CFD is disabled.

Configuring service instances

About this task

Before configuring the MEPs and MIPs, you must first configure service instances. A service instance is a set of service access points (SAPs), and belongs to an MA in an MD.

The MD and MA define the level attribute and VLAN attribute of the messages handled by the MPs in a service instance. The MPs of the MA that carries no VLAN attribute do not belong to any VLAN.

Procedure

1. Enter system view.

   system-view
2. Create an MD.

   cfd md *md-name* [**index** *index-value*] **level** *level-value* [**md-id** { **dns** *dns-name* | **mac** *mac-address subnumber* | **none** }]
3. Create a service instance.

   cfd service-instance *instance-id* **ma-id** { **icc-based** *ma-name* | **integer** *ma-num* | **string** *ma-name* | **vlan-based** [*vlan-id*] } [**ma-index** *index-value*] **md** *md-name* [**vlan** *vlan-id*]

Configuring MEPs

About this task

CFD is implemented through various operations on MEPs. As a MEP is configured on a service instance, the MD level and VLAN attribute of the service instance become the attribute of the MEP.

Restrictions and guidelines

- You can specify an interface as the MEP for only one of the non-VLAN-specific MAs at the same level. In addition, the MEP must be outward facing.
- If a MEP in a non-VLAN-specific MA does not receive a CCM message within 3.5 CCM intervals from a remote MEP, the local MEP sets its interface to link down state. This behavior of the local MEP facilitates fast switchover for RRPP or Smart Link.

Prerequisites

Before you configure MEPs, you must configure service instances.

Procedure

1. Enter system view.
   system-view
2. Configure a MEP list.
   cfd meplist *mep-list* **service-instance** *instance-id*
   The created MEP must be included in the configured MEP list.
3. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
4. Create a MEP.
   cfd mep *mep-id* **service-instance** *instance-id* { **inbound** | **outbound** }

Configuring MIP auto-generation rules

About this task

As functional entities in a service instance, MIPs respond to various CFD frames, such as LTM and LBM frames. You can configure MIP auto-generation rules for the system to automatically create MIPs.

Any of the following events can cause MIPs to be created or deleted after you have configured the **cfd mip-rule** command:

- Enabling or disabling CFD.
- Creating or deleting MEPs on a port.
- Changes occur to the VLAN attribute of a port.
- The rule specified in the **cfd mip-rule** command changes.

Restrictions and guidelines

- An MA carrying no VLAN attribute is typically used to detect direct link status. The system cannot generate MIPs for such MAs.
- For an MA carrying VLAN attribute, the system does not generate MIPs if the same or a higher level MEP exists on the interface.

Procedure

1. Enter system view.
   system-view

2. Configure MIP auto-generation rules.

   cfd mip-rule { **default** | **explicit** } **service-instance** *instance-id*

   By default, no rules for generating MIPs are configured, and the system does not automatically create any MIP.

Configuring CFD functions

Configuring CC

About this task

After the CC function is configured, MEPs in an MA can periodically send CCM frames to maintain connectivity.

You must configure CC before you use the MEP ID of the remote MEP to configure other CFD functions. This restriction does not apply when you use the MAC address of the remote MEP to configure other CFD functions.

When the lifetime of a CCM frame expires, the link to the sending MEP is considered disconnected. When setting the CCM interval, use the settings described in Table 1.

Table 1 CCM interval field encoding

CCM interval field	Transmission interval	Maximum CCM lifetime
1	10/3 milliseconds	35/3 milliseconds
2	10 milliseconds	35 milliseconds
3	100 milliseconds	350 milliseconds
4	1 second	3.5 seconds
5	10 seconds	35 seconds
6	60 seconds	210 seconds
7	600 seconds	2100 seconds

NOTE:

- The value range for the interval field is 1 to 7. If you set the value to 1 or 2, the continuity check might work incorrectly due to hardware restrictions.
- The CCM messages with an interval field value of 1 to 3 are short-interval CCM messages. The CCM messages with an interval field value of 4 to 7 are long-interval CCM messages.

Restrictions and guidelines

When you configure the CCM interval, follow these restrictions and guidelines:

- Configure the same CCM interval field value for all MEPs in the same MA.
- After the CCM interval field is modified, the MEP that does not support hardware CC must wait for another CCM interval before sending CCMs.
- If the device cannot process short-interval CCM messages, setting the CCM interval field value to smaller than 4 might cause the CC function to operate unsteadily.

Only outward-facing MEPs on a physical port support hardware CC. The hardware CC function does not take effect if the physical port is a member port of an aggregation group.

Procedure

1. Enter system view.

system-view

2. (Optional.) Set the CCM interval field.
   cfd cc interval *interval-value* **service-instance** *instance-id*
   By default, the interval field value is 4.
3. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
4. Enable CCM sending on a MEP.
   cfd cc service-instance *instance-id* **mep** *mep-id* **enable**
   By default, CCM sending is disabled on a MEP.
5. (Optional.) Enable hardware CC on a MEP.
   a. Return to system view.
      quit
   b. Enter Layer 2 Ethernet interface view.
      interface *interface-type interface-number*
   c. Enable hardware CC on a MEP.
      cfd hardware-cc service-instance *instance-id* **remote-mep** *mep-list*
      By default, hardware CC is disabled on a MEP.

Configuring LB

To verify the link state between the local MEP and the remote MEP, execute the following command in any view:

cfd loopback service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**number** *number*]

Configuring LT

About this task

LT can trace the path between source and target MEPs, and can locate link faults by automatically sending LT messages. The two functions are implemented in the following way:

- **Tracing path**—The source MEP first sends LTM messages to the target MEP. Based on the LTR messages in response to the LTM messages, the path between the two MEPs is identified.
- **LT messages automatic sending**—If the source MEP fails to receive CCM frames from the target MEP within 3.5 times the transmission interval, it considers the link faulty. The source MEP then sends LTM frames, with the TTL field set to the maximum value 255, to the target MEP. Based on the returned LTRs, the fault source is located.

Prerequisites

Before you configure LT on a MEP in an MA carrying VLAN attribute, create the VLAN to which the MA belongs.

Procedure

1. Identify the path between a source MEP and a target MEP.
   cfd linktrace service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**ttl** *ttl-value*] [**hw-only**]
   This command is available in any view.
2. Enter system view.
   system-view

3. Enable LT messages automatic sending.

   cfd linktrace auto-detection [**size** *size-value*]

   By default, LT messages automatic sending is disabled.

Configuring AIS

About this task

The AIS function suppresses the number of error alarms reported by MEPs.

Restrictions and guidelines

If you enable AIS, the MEPs in a service instance cannot send AIS frames in the following conditions:

- No AIS frame transmission level is configured.
- The AIS frame transmission level is lower than the MD level of the service instance.

If you enable AIS and configure an AIS frame transmission level equal to the MD level of a service instance, the MEPs in the service instance:

- Can suppress error alarms.
- Cannot send AIS frames to MDs with higher level.

Procedure

1. Enter system view.

   system-view

2. Enable AIS.

   cfd ais enable

   By default, AIS is disabled.

3. Configure the AIS frame transmission level.

   cfd ais level *level-value* **service-instance** *instance-id*

   By default, the AIS frame transmission level is not configured.

   The AIS frame transmission level must be higher than the MD level of the service instance.

4. Configure the AIS frame transmission interval.

   cfd ais period *period-value* **service-instance** *instance-id*

   By default, the AIS frame transmission interval is 1 second.

Configuring LM

About this task

The LM function measures frame loss between MEPs. Frame loss statistics include the number of lost frames, the frame loss ratio, and the average number of lost frames for the source and target MEPs.

Procedure

To configure LM, execute the following command in any view:

cfd slm service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**dot1p** *dot1p-value*] [**number** *number*] [**interval** *interval*]

Configuring one-way DM

About this task

The one-way DM function measures the one-way frame delay between two MEPs, and monitors and manages the link transmission performance.

Restrictions and guidelines

Follow these guidelines when you configure one-way DM on a MEP:

- One-way DM requires that the time setting at the transmitting MEP and the receiving MEP be the same. For the purpose of frame delay variation measurement, the requirement can be relaxed.
- To view the test result, use the **display cfd dm one-way history** command on the target MEP.

Procedure

To configure one-way DM, execute the following command in any view:

cfd dm one-way service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**number** *number*]

Configuring two-way DM

About this task

The two-way DM function measures the two-way frame delay, average two-way frame delay, and two-way frame delay variation between two MEPs. It also monitors and manages the link transmission performance.

Procedure

To configure two-way DM, execute the following command in any view:

cfd dm two-way service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } **dot1p** *dot1p-value*] [**number** *number*] [**interval** *interval*]

Configuring TST

About this task

The TST function detects bit errors on a link, and monitors and manages the link transmission performance.

Restrictions and guidelines

To view the test result, use the **display cfd tst** command on the target MEP.

Procedure

To configure TST, execute the following command in any view:

cfd tst service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**number** *number*] [**length-of-test** *length*] [**pattern-of-test** { **all-zero** | **prbs** } [**with-crc**]]

Configuring EAIS

Restrictions and guidelines

Follow these guidelines when you configure EAIS on a MEP:

- You can configure EAIS on a device that does not support or is not configured with CFD. However, EAIS must collaborate with the CFD function in the network, so you must configure CFD in the network.
- You can configure EAIS on the member port of an aggregation group, but the configuration does not take effect. If you configure EAIS on the port and then add it to an aggregation group, the EAIS configuration immediately fails to take effect. After the port leaves the aggregation group, the EAIS configuration takes effect.
- If the intersection of the configured VLANs where the EAIS frames can be transmitted and the VLANs to which the port belongs is empty, no EAIS frame is sent. If the intersection contains more than 70 VLANs and the EAIS frame transmission interval is 1 second, the CPU usage will be too high. As a best practice, set the EAIS frame transmission interval to 60 seconds in this case.

Procedure

1. Enter system view.

   system-view
2. Enable port status-AIS collaboration.

   cfd ais-track link-status global

   By default, port status-AIS collaboration is disabled.
3. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*
4. Configure the EAIS frame transmission level.

   cfd ais-track link-status level *level-value*

   By default, the EAIS frame transmission level is not configured.
5. Configure the EAIS frame transmission interval.

   cfd ais-track link-status period *period-value*

   By default, the EAIS frame transmission interval is not configured.
6. Specify the VLANs where the EAIS frames can be transmitted.

   cfd ais-track link-status vlan *vlan-list*

   By default, the EAIS frames can only be transmitted within the default VLAN of the port.

   The EAIS frames are transmitted within the intersection of the VLANs specified with this command and the existing VLANs on the device.

Enabling CC status change notification

About this task

In a CFD network, when the CC of a local MEP detects a link fault, this feature enables other MEPs in the service instance to notify the remote MEP that the CC status of the local MEP has changed to failed. If the port collaboration triggering event configured for the remote MEP is remote interface down status, the remote MEP will trigger port collaboration.

After you enable this feature, when the local MEP in a service instance detects a CC status change, other MEPs in the service instance will notify this status change to the remote MEP through CCMs.

Procedure

1. Enter system view.
   system-view
2. Enable CC status change notification.
   cfd mac-status-reference cc-status service-instance *instance-id*
   By default, CC status change notification is disabled.

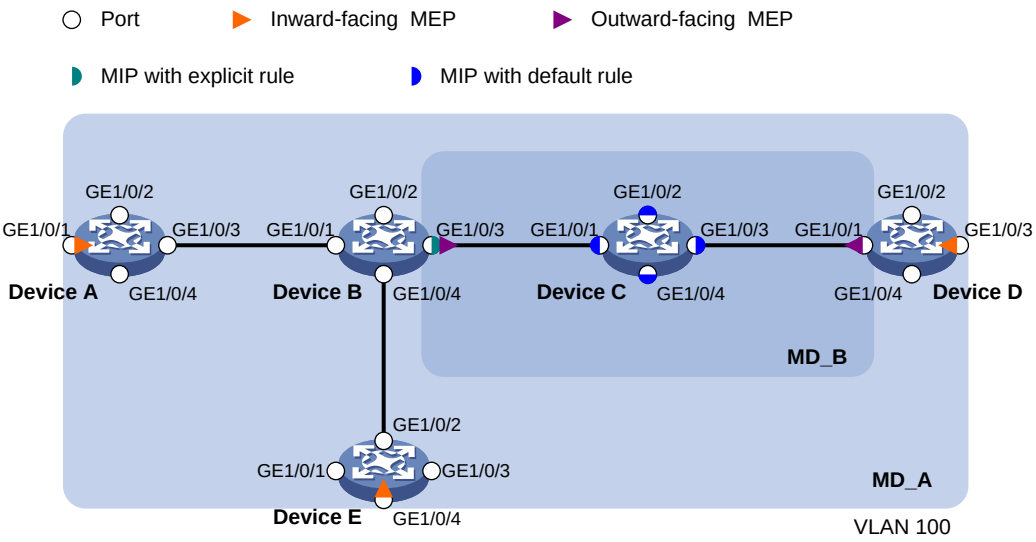
Display and maintenance commands for CFD

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the AIS configuration and information on the specified MEP.	**display cfd ais** [**service-instance** *instance-id* [**mep** *mep-id*]]
Display the AIS configuration and information associated with the status of the specified port.	**display cfd ais-track link-status** [**interface** *interface-type interface-number*]
Display the one-way DM result on the specified MEP.	**display cfd dm one-way history** [**service-instance** *instance-id* [**mep** *mep-id*]]
Display LTR information received by a MEP.	**display cfd linktrace-reply** [**service-instance** *instance-id* [**mep** *mep-id*]]
Display the content of the LTR messages received as responses to the automatically sent LTMs.	**display cfd linktrace-reply auto-detection** [**size** *size-value*]
Display MD configuration information.	**display cfd md**
Display the attribute and running information of the MEPs.	**display cfd mep** *mep-id* **service-instance** *instance-id*
Display MEP lists in a service instance.	**display cfd meplist** [**service-instance** *instance-id*]
Display MP information.	**display cfd mp** [**interface** *interface-type interface-number*]
Display information about a remote MEP.	**display cfd remote-mep service-instance** *instance-id* **mep** *mep-id*
Display service instance configuration.	**display cfd service-instance** [*instance-id*]
Display CFD status.	**display cfd status**
Display the TST result on the specified MEP.	**display cfd tst** [**service-instance** *instance-id* [**mep** *mep-id*]]
Clear the one-way DM result on the specified MEP.	**reset cfd dm one-way history** [**service-instance** *instance-id* [**mep** *mep-id*]]
Clear the TST result on the specified MEP.	**reset cfd tst** [**service-instance**

Task	Command
	instance-id [**mep** *mep-id*]]

CFD configuration examples



Example: Configuring CFD

Network configuration

As shown in Figure 4:

- The network comprises five devices and is divided into two MDs: MD_A (level 5) and MD_B (level 3). All ports belong to VLAN 100, and the MAs in the two MDs all serve VLAN 100. Assume that the MAC addresses of Device A through Device E are 0010-FC01-6511, 0010-FC02-6512, 0010-FC03-6513, 0010-FC04-6514, and 0010-FC05-6515, respectively.
- MD_A has three edge ports: GigabitEthernet 1/0/1 on Device A, GigabitEthernet 1/0/3 on Device D, and GigabitEthernet 1/0/4 on Device E. They are all inward-facing MEPs. MD_B has two edge ports: GigabitEthernet 1/0/3 on Device B and GigabitEthernet 1/0/1 on Device D. They are both outward-facing MEPs.
- In MD_A, Device B is designed to have MIPs when its port is configured with low level MEPs. Port GigabitEthernet 1/0/3 is configured with MEPs of MD_B, and the MIPs of MD_A can be configured on this port. You must configure the MIP generation rule of MD_A as explicit.
- The MIPs of MD_B are designed on Device C, and are configured on all ports. You must configure the MIP generation rule as default.
- Configure CC to monitor the connectivity among all the MEPs in MD_A and MD_B. Configure LB to locate link faults, and use the AIS and EAIS functions to suppress the error alarms that are reported.
- After the status information of the entire network is obtained, use LT, LM, one-way DM, two-way DM, and TST to detect link faults.

Figure 4 Network diagram

Procedure

1. Configure a VLAN and assign ports to it:

On each device shown in Figure 4, create VLAN 100 and assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to VLAN 100.

2. Enable CFD:

Enable CFD on Device A.

```
<DeviceA> system-view
[DeviceA] cfd enable
```

Configure Device B through Device E in the same way Device A is configured. (Details not shown.)

3. Configure service instances:

Create MD_A (level 5) on Device A, and create service instance 1 (in which the MA is identified by a VLAN and serves VLAN 100).

```
[DeviceA] cfd md MD_A level 5
[DeviceA] cfd service-instance 1 ma-id vlan-based md MD_A vlan 100
```

Configure Device E in the same way Device A is configured. (Details not shown.)

Create MD_A (level 5) on Device B, and create service instance 1 (in which the MA is identified by a VLAN and serves VLAN 100).

```
[DeviceB] cfd md MD_A level 5
[DeviceB] cfd service-instance 1 ma-id vlan-based md MD_A vlan 100
```

Create MD_B (level 3), and create service instance 2 (in which the MA is identified by a VLAN and serves VLAN 100).

```
[DeviceB] cfd md MD_B level 3
[DeviceB] cfd service-instance 2 ma-id vlan-based md MD_B vlan 100
```

Configure Device D in the same way Device B is configured. (Details not shown.)

Create MD_B (level 3) on Device C, and create service instance 2 (in which the MA is identified by a VLAN and serves VLAN 100).

```
[DeviceC] cfd md MD_B level 3
[DeviceC] cfd service-instance 2 ma-id vlan-based md MD_B vlan 100
```

4. Configure MEPs:

On Device A, configure a MEP list in service instance 1, and create inward-facing MEP 1001 in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] cfd meplist 1001 4002 5001 service-instance 1
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] cfd mep 1001 service-instance 1 inbound
[DeviceA-GigabitEthernet1/0/1] quit
```

On Device B, configure a MEP list in service instances 1 and 2.

```
[DeviceB] cfd meplist 1001 4002 5001 service-instance 1
[DeviceB] cfd meplist 2001 4001 service-instance 2
```

Create outward-facing MEP 2001 in service instance 2 on GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] cfd mep 2001 service-instance 2 outbound
[DeviceB-GigabitEthernet1/0/3] quit
```

On Device D, configure a MEP list in service instances 1 and 2.

```
[DeviceD] cfd meplist 1001 4002 5001 service-instance 1
[DeviceD] cfd meplist 2001 4001 service-instance 2
```

Create outward-facing MEP 4001 in service instance 2 on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] cfd mep 4001 service-instance 2 outbound
[DeviceD-GigabitEthernet1/0/1] quit
```

Create inward-facing MEP 4002 in service instance 1 on GigabitEthernet 1/0/3.

```
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] cfd mep 4002 service-instance 1 inbound
[DeviceD-GigabitEthernet1/0/3] quit
```

On Device E, configure a MEP list in service instance 1.

```
[DeviceE] cfd meplist 1001 4002 5001 service-instance 1
```

Create inward-facing MEP 5001 in service instance 1 on GigabitEthernet 1/0/4.

```
[DeviceE] interface gigabitethernet 1/0/4
[DeviceE-GigabitEthernet1/0/4] cfd mep 5001 service-instance 1 inbound
[DeviceE-GigabitEthernet1/0/4] quit
```

5. Configure MIPs:

Configure the MIP generation rule in service instance 1 on Device B as **`explicit`**.

```
[DeviceB] cfd mip-rule explicit service-instance 1
```

Configure the MIP generation rule in service instance 2 on Device C as **`default`**.

```
[DeviceC] cfd mip-rule default service-instance 2
```

6. Configure CC:

On Device A, enable the sending of CCM frames for MEP 1001 in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] cfd cc service-instance 1 mep 1001 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

On Device B, enable the sending of CCM frames for MEP 2001 in service instance 2 on GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] cfd cc service-instance 2 mep 2001 enable
[DeviceB-GigabitEthernet1/0/3] quit
```

On Device D, enable the sending of CCM frames for MEP 4001 in service instance 2 on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] cfd cc service-instance 2 mep 4001 enable
[DeviceD-GigabitEthernet1/0/1] quit
```

Enable the sending of CCM frames for MEP 4002 in service instance 1 on GigabitEthernet 1/0/3.

```
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] cfd cc service-instance 1 mep 4002 enable
[DeviceD-GigabitEthernet1/0/3] quit
```

On Device E, enable the sending of CCM frames for MEP 5001 in service instance 1 on GigabitEthernet 1/0/4.

```
[DeviceE] interface gigabitethernet 1/0/4
[DeviceE-GigabitEthernet1/0/4] cfd cc service-instance 1 mep 5001 enable
[DeviceE-GigabitEthernet1/0/4] quit
```

7. Configure hardware CC:

Configure hardware CC on GigabitEthernet 1/0/1 of Device D to enable MEP 4001 to receive CCM frames from MEP 2001.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] cfd hardware-cc service-instance 2 remote-mep 2001
[DeviceD-GigabitEthernet1/0/1] quit
```

8. Configure AIS:

Enable AIS on Device B. Configure the AIS frame transmission level as 5 and AIS frame transmission interval as 1 second in service instance 2.

```
[DeviceB] cfd ais enable
[DeviceB] cfd ais level 5 service-instance 2
[DeviceB] cfd ais period 1 service-instance 2
```

9. Configure EAIS:

Enable port status-AIS collaboration on Device B.

```
[DeviceB] cfd ais-track link-status global
```

On GigabitEthernet 1/0/3 of Device B, configure the EAIS frame transmission level as 5 and the EAIS frame transmission interval as 60 seconds. Specify the VLANs where the EAIS frames can be transmitted as VLAN 100.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] cfd ais-track link-status level 5
[DeviceB-GigabitEthernet1/0/3] cfd ais-track link-status period 60
[DeviceB-GigabitEthernet1/0/3] cfd ais-track link-status vlan 100
[DeviceB-GigabitEthernet1/0/3] quit
```

Verifying the configuration

1. Verify the LB function when the CC function detects a link fault:

Enable LB on Device A to check the status of the link between MEP 1001 and MEP 5001 in service instance 1.

```
[DeviceA] cfd loopback service-instance 1 mep 1001 target-mep 5001
Loopback to MEP 5001 with the sequence number start from 1001-43404:
Reply from 0010-fc05-6515: sequence number=1001-43404 time=5ms
Reply from 0010-fc05-6515: sequence number=1001-43405 time=5ms
Reply from 0010-fc05-6515: sequence number=1001-43406 time=5ms
Reply from 0010-fc05-6515: sequence number=1001-43407 time=5ms
Reply from 0010-fc05-6515: sequence number=1001-43408 time=5ms
Sent: 5        Received: 5        Lost: 0
```

2. Verify the LT function after the CC function obtains the status information of the entire network:

Identify the path between MEP 1001 and MEP 5001 in service instance 1 on Device A.

```
[DeviceA] cfd linktrace service-instance 1 mep 1001 target-mep 5001
Linktrace to MEP 5001 with the sequence number 1001-43462:
MAC address               TTL     Last MAC         Relay action
0010-fc05-6515            63      0010-fc02-6512   Hit
```

3. Verify the LM function after the CC function obtains the status information of the entire network:

Test the frame loss from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd slm service-instance 1 mep 1001 target-mep 4002
Reply from 0010-fc04-6514
Far-end frame loss: 10    Near-end frame loss: 20
Reply from 0010-fc04-6514
Far-end frame loss: 40    Near-end frame loss: 40
Reply from 0010-fc04-6514
Far-end frame loss: 0     Near-end frame loss: 10
Reply from 0010-fc04-6514
Far-end frame loss: 30    Near-end frame loss: 30

Average
Far-end frame loss: 20    Near-end frame loss: 25
```

```
Far-end frame loss rate: 25.00%    Near-end frame loss rate: 32.00%
Send LMMs: 5        Received: 5        Lost: 0
```

4. Verify the one-way DM function after the CC function obtains the status information of the entire network:

Test the one-way frame delay from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd dm one-way service-instance 1 mep 1001 target-mep 4002
5 1DMs have been sent. Please check the result on the remote device.
```

Display the one-way DM result on MEP 4002 in service instance 1 on Device D.

```
[DeviceD] display cfd dm one-way history service-instance 1 mep 4002
Service instance: 1
MEP ID: 4002
Sent 1DM total number: 0
Received 1DM total number: 5
Frame delay: 10ms 9ms 11ms 5ms 5ms
Delay average: 8ms
Delay variation: 5ms 4ms 6ms 0ms 0ms
Variation average: 3ms
```

5. Verify the two-way DM function after the CC function obtains the status information of the entire network:

Test the two-way frame delay from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd dm two-way service-instance 1 mep 1001 target-mep 4002
Frame delay:
Reply from 0010-fc04-6514: 2406us
Reply from 0010-fc04-6514: 2215us
Reply from 0010-fc04-6514: 2112us
Reply from 0010-fc04-6514: 1812us
Reply from 0010-fc04-6514: 2249us
Average: 2158us
Sent DMMs: 5        Received: 5        Lost: 0

Frame delay variation: 191us 103us 300us 437us
Average: 257us
```

6. Verify the TST function after the CC function obtains the status information of the entire network:

Test the bit errors on the link from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd tst service-instance 1 mep 1001 target-mep 4002
5 TSTs have been sent. Please check the result on the remote device.
```

Display the TST result on MEP 4002 in service instance 1 on Device D.

```
[DeviceD] display cfd tst service-instance 1 mep 4002
Service instance: 1
MEP ID: 4002
Sent TST total number: 0
Received TST total number: 5
Received from 0010-fc01-6511, Bit True,  sequence number 0
Received from 0010-fc01-6511, Bit True,  sequence number 1

Configuring DLDP

About DLDP

Physical layer detection mechanisms, such as auto-negotiation, can detect physical signals and faults. However, they cannot detect communication failures for unidirectional links where the physical layer is in connected state.

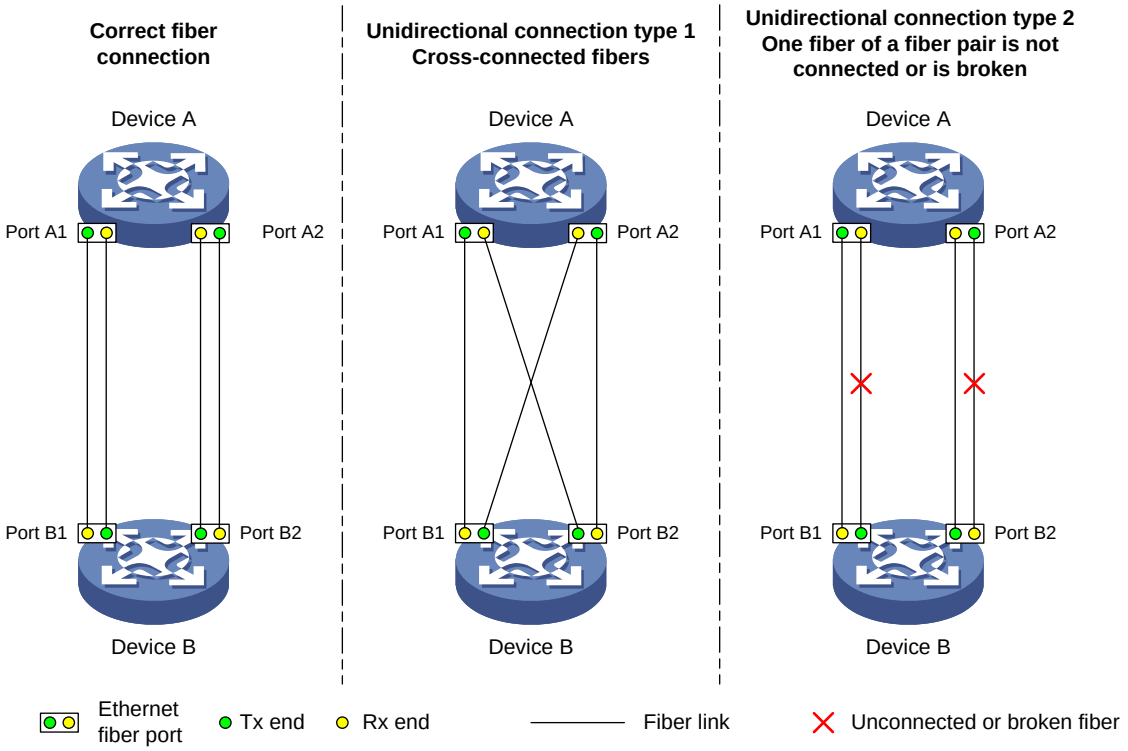
As an H3C-proprietary data link layer protocol, the Device Link Detection Protocol (DLDP) can do the following:

- Monitor status of the fiber link or twisted-pair link at the link layer.
- Cooperate with physical layer protocols to detect whether the link is correctly connected and whether the two ends of the link can exchange packets correctly.

When DLDP detects unidirectional links, it can automatically shut down the faulty port to avoid network problems. Alternatively, a user can manually shut down the faulty port.

Application scenario

A link becomes unidirectional when only one end of the link can receive packets from the other end.



Unidirectional fiber links occur in the following cases:

- Fibers are cross-connected.
- A fiber is not connected at one end or one fiber of a fiber pair is broken.

Figure 1 shows a correct fiber connection and two types of unidirectional fiber connections.

When DLDP detects unidirectional links, it can automatically shut down the faulty port to avoid network problems. Alternatively, a user can manually shut down the faulty port.

Figure 1 Correct and incorrect fiber connections

Basic concepts

DLDP neighbor states

If port A can receive link-layer packets from port B on the same link, port B is a DLDP neighbor of port A. Two ports that can exchange packets are neighbors.

Table 1 DLDP neighbor states

DLDP timer	Description
Confirmed	The link to a DLDP neighbor is bidirectional.
Unconfirmed	The state of the link to a newly discovered neighbor is not determined.

DLDP port states

A DLDP-enabled port is called a DLDP port. A DLDP port can have multiple neighbors, and its state varies by the DLDP neighbor state.

Table 2 DLDP port states

State	Description
Initial	DLDP is enabled on the port, but is disabled globally.
Inactive	DLDP is enabled on the port and globally, and the link is physically down.
Bidirectional	DLDP is enabled on the port and globally, and at least one neighbor in Confirmed state exists.
Unidirectional	DLDP is enabled on the port and globally, and no neighbor in Confirmed state exists. In this state, a port does not send or receive packets other than DLDP packets any more.

DLDP timers

Table 3 DLDP timers

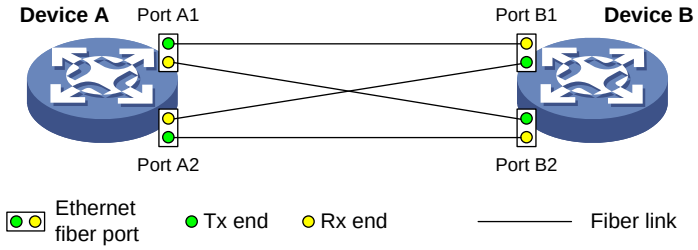
DLDP timer	Description
Advertisement timer	Advertisement packet sending interval (the default is 5 seconds and is configurable).
Probe timer	Probe packet sending interval. This timer is set to 1 second.
Echo timer	The Echo timer is triggered when a probe is launched for a new neighbor. The neighbor information is deleted when the timer expires. This timer is set to 10 seconds.
Entry timer	When a new neighbor joins, a neighbor entry is created and the corresponding Entry timer is triggered if the neighbor is in Confirmed state. When an Advertisement is received, the device updates the corresponding neighbor entry and the Entry timer. When the Entry timer expires, the Enhanced timer and Echo timer are triggered for the neighbor. The value of an Entry timer is three times that of the Advertisement timer.
Enhanced timer	Probe packet sending interval. This timer is set to 1 second. When the Entry timer expires, the Enhanced timer is triggered and probe packets are sent. At the same time, the Echo timer is triggered.
DelayDown timer	If a port is physically down, the device triggers the DelayDown timer, rather than removing the corresponding neighbor entry. The default DelayDown timer is 1 second and is configurable. When the DelayDown timer expires, the device removes the corresponding DLDP neighbor information if the port is down, and does not perform any operation if the port is up.
RecoverProbe timer	This timer is set to 2 seconds. A port in unidirectional state regularly sends RecoverProbe packets to detect whether a unidirectional link has been restored to bidirectional.

DLDP authentication mode

You can use DLDP authentication to prevent network attacks and illegal detecting.

Table 4 DLDP authentication mode

Authentication mode	Processing at the DLDP packet sending side	Processing at the DLDP packet receiving side
Non-authentication	The sending side sets the Authentication field of DLDP packets to 0.	The receiving side examines the authentication information of received DLDP packets and drops packets where the authentication information conflicts with the local configuration.
Plaintext authentication	The sending side sets the Authentication field to the password configured in plain text.	
MD5 authentication	The sending side encrypts the user configured password by using MD5 algorithm, and assigns the digest to the Authentication field.	



How DLDP works

Detecting one neighbor

When two devices are connected through an optical fiber or a network cable, enable DLDP to detect unidirectional links to the neighbor. The following illustrates the unidirectional link detection process in two cases:

- Unidirectional links occur before you enable DLDP.

  Figure 2 Cross-connected fibers

  As shown in Figure 2, before you enable DLDP, the optical fibers between Device A and Device B are cross-connected. After you enable DLDP, the four ports are all up and in unidirectional state, and they send RecoverProbe packets. Take Port A1 as an example to illustrate the unidirectional link detection process.

  a. Port A1 receives the RecoverProbe packet from Port B2, and returns a RecoverEcho packet.

  b. Port B2 cannot receive any RecoverEcho packet from Port A1, so Port B2 cannot become the neighbor of Port A1.

  c. Port B1 can receive the RecoverEcho packet from Port A1, but Port B1 is not the intended destination, so Port B1 cannot become the neighbor of Port A1.

  The same process occurs on the other three ports. The four ports are all in unidirectional state.

- Unidirectional links occur after you enable DLDP.

  Figure 3 Broken fiber

  As shown in Figure 3, Device A and Device B are connected through an optical fiber. After you enable DLDP, Port A1 and Port B1 establish the bidirectional neighborship in the following way:

  a. Port A1 that is physically up enters the unidirectional state and sends a RecoverProbe packet.

  b. After receiving the RecoverProbe packet, Port B1 returns a RecoverEcho packet.

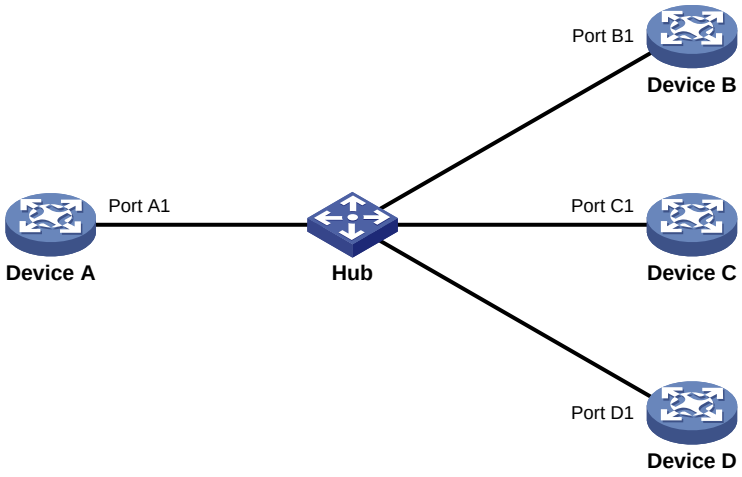
  c. After Port A1 receives the RecoverEcho packet, it examines the neighbor information in the packet. If the neighbor information matches the local information, Port A1 establishes the neighborship with Port B1 and transits to bidirectional state. Port A1 then starts the Entry timer and periodically sends Advertisement packets.

d. After Port B1 receives the Advertisement packet, it establishes the Unconfirmed neighborship with Port A1. Port B1 then starts the Echo timer and Probe timer, and periodically sends Probe packets.

e. After receiving the Probe packet, Port A1 returns an Echo packet.

f. After Port B1 receives the Echo packet, it examines the neighbor information in the packet. If the neighbor information matches the local information, the neighbor state of Port A1 becomes Confirmed. Port B1 then transits to bidirectional state, starts the Entry timer, and periodically sends Advertisement packets.

The bidirectional neighborship between Port A1 and Port B1 is now established.



After that, when Port B1's Rx end fails to receive signals, Port B1 is physically down and enters the Inactive state. Because Port B1's Tx end can still send signals to Port A1, Port A1 stays up. After the Entry timer for Port B1 expires, Port A1 starts the Enhanced timer and Echo timer, and sends a probe packet to Port B1. Because Port A1's Tx line is broken, Port A1 cannot receive the Echo packet from Port B1 after the Echo timer expires. Port A1 then enters the unidirectional state, and sends a Disable packet to Port B1. At the same time, Port A1 deletes the neighborship with Port B1, and starts the RecoverProbe timer. Port B1 stays in Inactive state during this process.

When an interface is physically down, but the Tx end of the interface is still operating, DLDP sends a LinkDown packet to inform the peer to delete the relevant neighbor entry.

Detecting multiple neighbors

When multiple devices are connected through a hub, enable DLDP on all interfaces connected to the hub to detect unidirectional links among the neighbors. When no Confirmed neighbor exists, an interface enters the unidirectional state.

Figure 4 Network diagram

As shown in Figure 4, Device A through Device D are connected through a hub, and enabled with DLDP. When Port A1, Port B1, and Port C1 detect that the link to Port D1 fails, they delete the neighborship with Port D1, but stay in bidirectional state.

Restrictions and guidelines: DLDP configuration

When you configure DLDP, follow these configuration restrictions and guidelines:

- For DLDP to operate correctly, enable DLDP on both sides and make sure the following settings are consistent:
  - Interval to send Advertisement packets.
  - DLDP authentication mode.

- Password.

- For DLDP to operate correctly, configure the full duplex mode for the ports at the two ends of the link, and configure the same speed for the two ports.

DLDP tasks at a glance

To configure DLDP, perform the following tasks:

1. Enabling DLDP
2. (Optional.) Setting the interval to send advertisement packets
3. (Optional.) Setting the DelayDown timer
4. (Optional.) Setting the port shutdown mode
5. (Optional.) Configuring DLDP authentication

Enabling DLDP

About this task

After a port is enabled with DLDP, the port enters Initial state and then transitions to Unidirectional state. By default, DLDP blocks a port immediately when the port transitions to Unidirectional state. This behavior causes a traffic disruption that lasts until the port enters Bidirectional state when establishing a Confirmed neighbor.

You can set the delay time for DLDP to block a port upon an Initial-to-Unidirectional state transition. DLDP does not block the port until the delay time expires.

Procedure

1. Enter system view.

   system-view

2. Enable DLDP globally.

   dldp global enable

   By default, DLDP is globally disabled.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Enable DLDP and set the delay time for DLDP to block the port upon an Initial-to-Unidirectional state transition.

   dldp enable [**initial-unidirectional-delay** *time*]

   By default, DLDP is disabled on a port, and when DLDP is enabled, a port is blocked immediately upon an Initial-to-Unidirectional state transition.

Setting the interval to send advertisement packets

About this task

To make sure DLDP can detect unidirectional links before network performance deteriorates, set the advertisement interval appropriate for your network environment. As a best practice, use the default interval.

Procedure

1. Enter system view.

   system-view

2. Set the interval to send Advertisement packets.
   dldp interval *interval*
   By default, the interval is 5 seconds.

Setting the DelayDown timer

About this task

When the Tx line fails, some ports might go down and then come up again, causing optical signal jitters on the Rx line. To prevent the device from removing neighbor entries in such cases, set the DelayDown timer for the device. The device starts the DelayDown timer when a port goes down due to a Tx line failure. If the port remains down when the timer expires, the device removes the DLDP neighbor information. If the port comes up, the device takes no action.

Procedure

1. Enter system view.
   system-view
2. Set the DelayDown timer.
   dldp delaydown-timer *time*
   The default is 1 second.
   The DelayDown timer setting applies to all DLDP-enabled ports.

Setting the port shutdown mode

About this task

On detecting a unidirectional link, DLDP shuts down the ports in one of the following modes:

- **Auto mode**—When DLDP detects a unidirectional link, it shuts down the unidirectional port. When the link becomes bidirectional, DLDP brings up the port that was shut down.
- **Manual mode**—When DLDP detects a unidirectional link, it does not shut down the port. You need to manually shut it down. To verify the link status, use the **undo shutdown** command to bring up the port. If the link becomes bidirectional, the port becomes bidirectional. Use this mode to prevent normal links from being shut down because of false unidirectional link reports in the following cases:
  - The network performance is low.
  - The device is busy.
  - The CPU usage is high.
- **Hybrid mode**—When DLDP detects a unidirectional link, it shuts down the unidirectional port and stops link detection. To verify the link status, use the **undo shutdown** command to bring up the port. If the link becomes bidirectional, the port becomes bidirectional.

Restrictions and guidelines

You can set the port shutdown mode for all interfaces in system view or for a single interface in interface view. The setting in interface view takes precedence over the setting in system view.

To enable remote OAM loopback on a DLDP port, set the port shutdown mode to **manual**. Otherwise, DLDP automatically shuts down the port when it receives a packet sent by itself. This causes remote OAM loopback failure. For more information about Ethernet OAM, see "Configuring Ethernet OAM."

Setting the global port shutdown mode

1. Enter system view.

system-view

2. Set the global port shutdown mode.
   dldp unidirectional-shutdown { **auto** | **hybrid** | **manual** }
   The default mode is **auto**.

Setting the port shutdown mode for an interface

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Set the the port shutdown mode for the interface.
   dldp port unidirectional-shutdown { **auto** | **hybrid** | **manual** }
   By default, the global setting is used.

Configuring DLDP authentication

About this task

You can guard your network against attacks and malicious probes by configuring an appropriate DLDP authentication mode, which can be plain text authentication or MD5 authentication. If your network is safe, you can choose not to authenticate.

Procedure

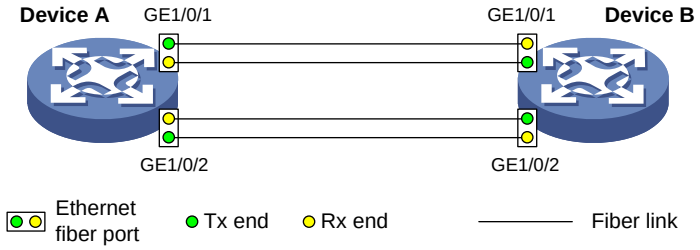
1. Enter system view.
   system-view
2. Configure a DLDP authentication mode.
   dldp authentication-mode { **md5** | **none** | **simple** }
   The default authentication mode is **none**.
3. Configure the password for DLDP authentication.
   dldp authentication-password { **cipher** | **simple** } *string*
   By default, no password is configured for DLDP authentication.
   If you do not configure the authentication password after you configure the authentication mode, the authentication mode is **none** no matter which authentication mode you configure.

Display and maintenance commands for DLDP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display the DLDP configuration globally and of a port.	**display dldp** [**interface** *interface-type interface-number*]
Display the statistics on DLDP packets passing through a port.	**display dldp statistics** [**interface** *interface-type interface-number*]
Clear the statistics on DLDP packets passing through a port.	**reset dldp statistics** [**interface** *interface-type interface-number*]

DLDP configuration examples



Example: Configuring the auto port shutdown mode

Network configuration

As shown in Figure 5, Device A and Device B are connected through two fiber pairs.

Configure DLDP to automatically shut down the faulty port upon detecting a unidirectional link, and automatically bring up the port after you clear the fault.

Figure 5 Network diagram

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp global enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] duplex full
   [DeviceA-GigabitEthernet1/0/2] speed 1000
   [DeviceA-GigabitEthernet1/0/2] dldp enable
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

   # Set the global port shutdown mode to auto.

   ```
   [DeviceA] dldp unidirectional-shutdown auto
   ```

2. Configure Device B:

   # Enable DLDP globally.

   ```
   <DeviceB> system-view
   [DeviceB] dldp global enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

   ```
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] duplex full
   ```

```
[DeviceB-GigabitEthernet1/0/1] speed 1000
[DeviceB-GigabitEthernet1/0/1] dldp enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] duplex full
[DeviceB-GigabitEthernet1/0/2] speed 1000
[DeviceB-GigabitEthernet1/0/2] dldp enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to auto.

```
[DeviceB] dldp unidirectional-shutdown auto
```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Auto
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
```

```
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jul 11 17:40:31:089 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the
interface Physical state on the interface GigabitEthernet1/0/1 changed to down.
%Jul 11 17:40:31:091 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to down.
%Jul 11 17:40:31:677 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
Physical state on the interface GigabitEthernet1/0/2 changed to down.
%Jul 11 17:40:31:678 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 11 17:40:38:544 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
Physical state on the interface GigabitEthernet1/0/1 l changed to up.
%Jul 11 17:40:38:836 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
Physical state on the interface GigabitEthernet1/0/2 changed to up.
```

The output shows the following:

- The port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is down and then up.
- The link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is always down.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Auto
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)

Interface GigabitEthernet1/0/2
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)
```

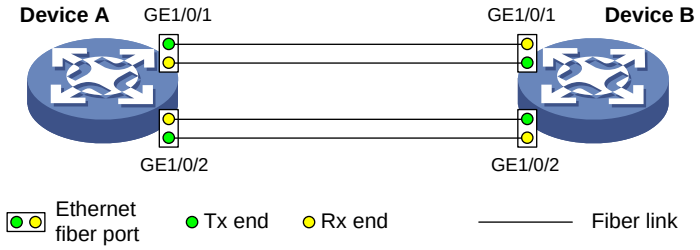
The output shows that the DLDP port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is unidirectional. DLDP detects unidirectional links on them and automatically shuts down the two ports.

The unidirectional links are caused by cross-connected fibers. Correct the fiber connections. As a result, the ports shut down by DLDP automatically recover, and Device A displays the following log information:

```
<DeviceA>%Jul 11 17:42:57:709 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the
interface GigabitEthernet1/0/1 changed to down.
%Jul 11 17:42:58:603 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to down.
```

```
%Jul 11 17:43:02:342 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 11 17:43:02:343 2012 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/1. The neighbor's system MAC is 0023-8956-3600, and the
port index is 1.
%Jul 11 17:43:02:344 2012 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a
bidirectional link on interface GigabitEthernet1/0/1.
%Jul 11 17:43:02:353 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 11 17:43:02:357 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to up.
%Jul 11 17:43:02:362 2012 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/2. The neighbor's system MAC is 0023-8956-3600, and the
port index is 2.
%Jul 11 17:43:02:362 2012 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a
bidirectional link on interface GigabitEthernet1/0/2.
%Jul 11 17:43:02:368 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to up.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are now up and their DLDP neighbors are determined.



Example: Configuring the manual port shutdown mode

Network configuration

As shown in Figure 6, Device A and Device B are connected through two fiber pairs.

Configure DLDP to detect unidirectional links. When a unidirectional link is detected, the administrator must manually shut down the port.

Figure 6 Network diagram

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] duplex full
[DeviceA-GigabitEthernet1/0/2] speed 1000
[DeviceA-GigabitEthernet1/0/2] dldp enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to manual.

```
[DeviceA] dldp unidirectional-shutdown manual
```

2. Configure Device B:

Enable DLDP globally.

```
<DeviceB> system-view
[DeviceB] dldp global enable
```

Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] duplex full
[DeviceB-GigabitEthernet1/0/1] speed 1000
[DeviceB-GigabitEthernet1/0/1] dldp enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] duplex full
[DeviceB-GigabitEthernet1/0/2] speed 1000
[DeviceB-GigabitEthernet1/0/2] dldp enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to manual.

```
[DeviceB] dldp unidirectional-shutdown manual
```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Manual
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
```

```
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are in bidirectional state, which means both links are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jul 12 08:29:17:786 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the
interface GigabitEthernet1/0/1 changed to down.
%Jul 12 08:29:17:787 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to down.
%Jul 12 08:29:17:800 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 12 08:29:17:800 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 12 08:29:25:004 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 12 08:29:25:005 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 12 08:29:25:893 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to up.
%Jul 12 08:29:25:894 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to up.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are down and then up.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Manual
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
```

```
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)

Interface GigabitEthernet1/0/2
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)
```

The output shows that the DLDP port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is unidirectional. DLDP detects unidirectional links on the two ports but does not shut them down.

The unidirectional links are caused by cross-connected fibers. Manually shut down the two ports:

Shut down GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] shutdown
```

The following log information is displayed on Device A:

```
[DeviceA-GigabitEthernet1/0/1]%Jul 12 08:34:23:717 2012 DeviceA IFNET/3/PHY_UPDOWN:
Physical state on the interface GigabitEthernet1/0/1 changed to down.
%Jul 12 08:34:23:718 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface

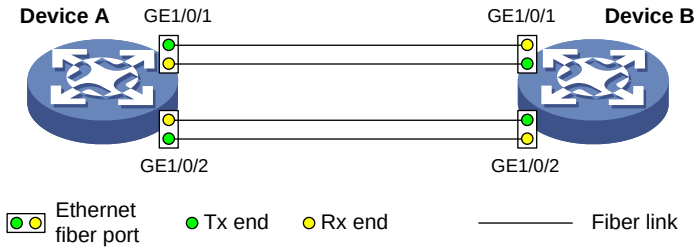
bidirectional link on interface GigabitEthernet1/0/1.
```

The output shows that the port status and link status of GigabitEthernet 1/0/1 are now up and its DLDP neighbors are determined.



Example: Configuring the hybrid port shutdown mode

Network configuration

As shown in Figure 7Figure 6, Device A and Device B are connected through two fiber pairs.

Configure DLDP to detect unidirectional links. When a unidirectional link is detected, DLDP automatically shuts down the unidirectional port. The administrator needs to bring up the port after clearing the fault.

Figure 7 Network diagram

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] duplex full
   ```

```
[DeviceA-GigabitEthernet1/0/2] speed 1000
[DeviceA-GigabitEthernet1/0/2] dldp enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to hybrid.

```
[DeviceA] dldp unidirectional-shutdown hybrid
```

2. Configure Device B:

Enable DLDP globally.

```
<DeviceB> system-view
[DeviceB] dldp global enable
```

Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] duplex full
[DeviceB-GigabitEthernet1/0/1] speed 1000
[DeviceB-GigabitEthernet1/0/1] dldp enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] duplex full
[DeviceB-GigabitEthernet1/0/2] speed 1000
[DeviceB-GigabitEthernet1/0/2] dldp enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to hybrid.

```
[DeviceB] dldp unidirectional-shutdown hybrid
```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Hybrid
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
```

```
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are in bidirectional state, which means both links are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jan  4 07:16:06:556 2011 DeviceA DLDP/5/DLDP_NEIGHBOR_AGED: A neighbor on
interface
GigabitEthernet1/0/1 was deleted because the neighbor was aged. The neighbor's system MAC

unidirectional link on interface GigabitEthernet1/0/1. DLDP automatically shut down the
interface. Please manually bring up the interface.
%Jan  4 07:16:07:156 2011 DeviceA DLDP/3/DLDP_LINK_UNIDIRECTIONAL: DLDP detected a
unidirectional link on interface GigabitEthernet1/0/2. DLDP automatically shut down the
interface. Please manually bring up the interface.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are down.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Hybrid
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2
```

```
Interface GigabitEthernet1/0/1
 DLDP port state: Inactive
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 0 (Maximum number ever detected: 1)
Interface GigabitEthernet1/0/2
 DLDP port state: Inactive
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 0 (Maximum number ever detected: 1)
```

The output shows that DLDP detects a unidirectional link and shuts down GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

The unidirectional links are caused by cross-connected fibers. Bring up the two ports after correcting the fiber connection:

Bring up GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo shutdown
```

The following log information is displayed on Device A:

```
[DeviceA-GigabitEthernet1/0/1]%Jan  4 07:33:26:574 2011 DeviceA IFNET/3/PHY_UPDOWN:
Physical state on the interface GigabitEthernet1/0/1 changed to up.
%Jan 4 07:33:57:562 2011 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/1. The neighbor's system MAC is 0023-8956-3600, and the
port index is 162.
%Jan  4 07:33:57:563 2011 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a

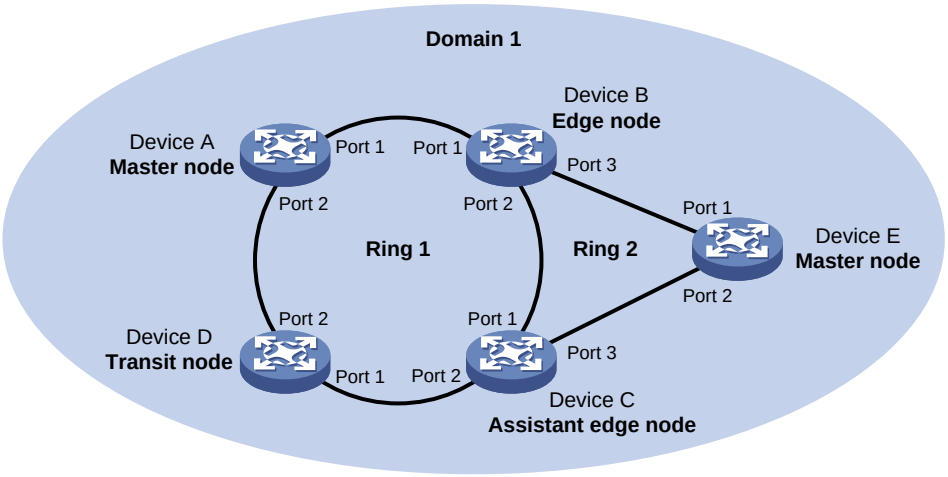
Configuring RRPP



About RRPP

The Rapid Ring Protection Protocol (RRPP) is an H3C-proprietary link layer protocol designed for Ethernet rings. RRPP can prevent broadcast storms caused by data loops when an Ethernet ring is healthy. RRPP can also rapidly restore the communication paths between the nodes when a link is disconnected on the ring. Compared with the spanning tree protocol, the convergence time of RRPP is fast and independent of the number of nodes in the Ethernet ring. RRPP is applicable to large-diameter networks.

RRPP networking

Figure 1 shows a typical RRPP network with two Ethernet rings and multiple nodes. RRPP detects ring status and sends topology change information by exchanging Rapid Ring Protection Protocol Data Units (RRPPDUs) among the nodes.

Figure 1 RRPP networking diagram

RRPP domain

An RRPP domain is uniquely identified by a domain ID. The interconnected devices with the same domain ID and control VLANs constitute an RRPP domain. An RRPP domain contains the following elements:

- Primary ring and subring.
- Control VLAN.
- Master node, transit node, edge node, and assistant edge node.
- Primary port, secondary port, common port, and edge port.

As shown in Figure 1, Domain 1 is an RRPP domain, containing two RRPP rings: Ring 1 and Ring 2. All the nodes on the two RRPP rings belong to the RRPP domain.

RRPP ring

A ring-shaped Ethernet topology is called an RRPP ring. RRPP rings include primary rings and subrings. You can configure a ring as either the primary ring or a subring by specifying its ring level. The primary ring is of level 0, and a subring is of level 1. An RRPP domain contains one or multiple

RRPP rings, one serving as the primary ring and the others serving as subrings. A ring can be in one of the following states:

- **`Health state`**—All physical links on the Ethernet ring are connected.
- **`Disconnect state`**—Some physical links on the Ethernet ring are not connected.

As shown in Figure 1, Domain 1 contains two RRPP rings: Ring 1 and Ring 2. The level is set to 0 for Ring 1 and 1 for Ring 2. Ring 1 is configured as the primary ring, and Ring 2 is configured as a subring.

Control VLAN and protected VLAN

1. Control VLAN

   In an RRPP domain, a control VLAN is dedicated to transferring RRPPDUs. On a device, the ports accessing an RRPP ring belong to the control VLANs of the ring, and only these ports can join the control VLANs.

   An RRPP domain is configured with the following control VLANs:

   - One primary control VLAN, which is the control VLAN for the primary ring.
   - One secondary control VLAN, which is the control VLAN for subrings.

   After you specify a VLAN as the primary control VLAN, the system automatically configures the secondary control VLAN. The VLAN ID is the primary control VLAN ID plus one. All subrings in the same RRPP domain share the same secondary control VLAN. IP address configuration is prohibited on the control VLAN interfaces.

2. Protected VLAN

   A protected VLAN is dedicated to transferring data packets. Both RRPP ports and non-RRPP ports can be assigned to a protected VLAN.

Node role

Each device on an RRPP ring is a node. The role of a node is configurable. RRPP has the following node roles:

- **Master node**—Each ring has only one master node. The master node initiates the polling mechanism and determines the operations to be performed after a topology change.
- **Transit node**—On the primary ring, transit nodes refer to all nodes except the master node. On the subring, transit nodes refer to all nodes except the master node and the nodes where the primary ring intersects with the subring. A transit node monitors the state of its directly connected RRPP links and notifies the master node of the link state changes, if any. Based on the link state changes, the master node determines the operations to be performed.
- **Edge node**—A special node residing on both the primary ring and a subring at the same time. An edge node acts as a master node or transit node on the primary ring and as an edge node on the subring.
- **Assistant edge node**—A special node residing on both the primary ring and a subring at the same time. An assistant edge node acts as a master node or transit node on the primary ring and as an assistant edge node on the subring. This node works in conjunction with the edge node to detect the integrity of the primary ring and to perform loop guard.

As shown in Figure 1, Ring 1 is the primary ring and Ring 2 is a subring. Device A is the master node of Ring 1. Device B, Device C, and Device D are the transit nodes of Ring 1. Device E is the master node of Ring 2, Device B is the edge node of Ring 2, and Device C is the assistant edge node of Ring 2.

Port role

1. Primary port and secondary port

   Each master node or transit node has two ports connected to an RRPP ring, a primary port and a secondary port. You can determine the role of a port.

   In terms of functionality, the primary port and the secondary port of a master node have the following differences:

- The primary port and the secondary port are designed to play the role of sending and receiving Hello packets, respectively.
- When an RRPP ring is in Health state, the secondary port logically denies protected VLANs and permits only the packets from the control VLANs.
- When an RRPP ring is in Disconnect state, the secondary port forwards packets from protected VLANs.

In terms of functionality, the primary port and the secondary port of a transit node are the same. Both are designed for transferring protocol packets and data packets over an RRPP ring.

As shown in Figure 1, Device A is the master node of Ring 1. Port 1 and Port 2 are the primary port and the secondary port of the master node on Ring 1, respectively. Device B, Device C, and Device D are the transit nodes of Ring 1. Their Port 1 and Port 2 are the primary port and the secondary port on Ring 1, respectively.

2. Common port and edge port

The ports connecting the edge node and assistant edge node to the primary ring are common ports. The ports connecting the edge node and assistant edge node only to the subrings are edge ports. You can determine the role of a port.

As shown in Figure 1, Device B and Device C reside on Ring 1 and Ring 2. Device B's Port 1 and Port 2 and Device C's Port 1 and Port 2 access the primary ring, so they are common ports. Device B's Port 3 and Device C's Port 3 access only the subring, so they are edge ports.

RRPP ring group

To reduce Edge-Hello traffic, you can configure a group of subrings on the edge node or assistant edge node. You must configure a device as the edge node of these subrings, and another device as the assistant edge node of these subrings. Additionally, the subrings of the edge node and assistant edge node must connect to the same subring packet tunnels in major ring (SRPTs). Edge-Hello packets of the edge node of these subrings travel to the assistant edge node of these subrings over the same link.

An RRPP ring group configured on the edge node is an edge node RRPP ring group. An RRPP ring group configured on an assistant edge node is an assistant edge node RRPP ring group. Only one subring in an edge node RRPP ring group is allowed to send Edge-Hello packets.

RRPPDUs

RRPPDUs of subrings are transmitted as data packets in the primary ring, and RRPPDUs of the primary ring can only be transmitted within the primary ring. In the primary ring, Common-Flush-FDB packets and Complete-Flush-FDB packets of subrings are sent to the CPU on each node for processing.

Table 1 RRPPDU types and their functions

Type	Description
Hello	The master node sends Hello packets (also known as Health packets) to detect the integrity of a ring in a network.
Fast-Hello	The master node sends Fast-Hello packets to detect the integrity of a ring in a network. Fast-Hello packets are used for the fast detection mechanism.
Link-Down	When a port on the transit node, edge node, or assistant edge node fails, the node initiates Link-Down packets to notify the master node of the disconnection of the ring.
Common-Flush-FDB	When an RRPP ring transits to Disconnect state, the master node initiates Common-Flush-FDB (FDB stands for Forwarding Database) packets. It uses the packets to instruct the transit nodes, edge nodes, and assistant edge nodes to update their own MAC address entries and ARP/ND entries.
Complete-Flush-FDB	When an RRPP ring transits to Health state, the master node sends

	Complete-Flush-FDB packets for the following purposes: • Instruct the transit nodes, edge nodes, and assistant edge nodes to update their MAC address entries and ARP/ND entries. • Instruct the transit nodes to unblock temporarily blocked ports.
Edge-Hello	The edge node sends Edge-Hello packets to examine the SRPTs between the edge node and the assistant edge node.
Fast-Edge-Hello	The edge node sends Fast-Edge-Hello packets to examine the SRPTs between it and the assistant edge node. Fast-Edge-Hello packets are used for the fast detection mechanism.
Major-Fault	The assistant edge node sends Major-Fault packets to notify the edge node of SRPT failure when an SRPT between assistant edge node and edge node is disconnected.

RRPP timers

When RRPP determines the link state of an Ethernet ring, it uses the following timers:

Hello timer

The Hello timer specifies the interval at which the master node sends Hello packets out of the primary port.

Fail timer

The Fail timer specifies the maximum delay of Hello packets sent from the primary port to the secondary port of the master node. If the secondary port receives the Hello packets sent by the local master node before the Fail timer expires, the ring is in Health state. If the secondary port does not receive the Hello packets before the Fail timer expires, the ring transits to Disconnect state.

In an RRPP domain, a transit node learns the Fail timer value on the master node through the received Hello packets. This ensures that all nodes in the ring network have consistent Fail timer settings.

Link-up delay timer

This feature prevents frequent switchover of RRPP traffic forwarding paths caused by unstable RRPP port states. This feature behaves differently depending on whether you specify the **`distribute`** keyword in the **`linkup-delay-timer`** command.

- If you do not specify the **`distribute`** keyword, the master node starts the link-up delay timer when a faulty port comes up and the master node receives Hello packets from the secondary port.
  - If the master node can still receive Hello packets from the secondary port after the link-up delay timer expires, the master node performs the following operations:
    - Changes the RRPP ring state from Disconnect to Health.
    - Switches the traffic from the secondary port to the primary port.
  - If the master node cannot receive Hello packets from the secondary port after the Fail timer expires and before the link-up delay timer expires, the master node performs the following operations:
    - Stops the link-up delay timer.
    - Keeps the RRPP ring in Disconnect state.
- If you specify the **`distribute`** keyword, all nodes in the RRPP domain can learn the value of the link-up delay timer through Hello packets. When the faulty port comes up, the master node performs the following operations:
  - The hosting RRPP node blocks the faulty port (the faulty port cannot send or receive any packets).

- Starts the link-up delay timer.

  If the port does not become faulty after the link-up delay timer expires, the hosting RRPP node sets the port state to up. The master node can receive Hello packets from its secondary port again. Then, the master node changes the RRPP ring state from Disconnect to Health and switches the traffic from the secondary port to the primary port.

  If the port becomes faulty again before the link-up delay timer expires, the hosting RRPP node blocks the port and stops the link-up delay timer.

Fast-Hello timer

The Fast-Hello timer specifies the interval at which the master node sends Fast-Hello packets out of the primary port.

Fast-Fail timer

The Fast-Fail timer specifies the maximum delay of Fast-Hello packets sent from the primary port to the secondary port of the master node. If the secondary port receives the Fast-Hello packets before the Fast-Fail timer expires, the ring is in Health state. Otherwise, the ring transits to Disconnect state.

A transit node cannot learn the Fast-Fail timer value on the master node through received Fast-Hello packets.

Fast-Edge-Hello timer

The Fast-Edge-Hello timer specifies the interval at which the edge node sends Fast-Edge-Hello packets out of the common port.

Fast-Edge-Fail timer

The Fast-Edge-Fail timer specifies the maximum delay of Fast-Edge-Hello packets from the common port of the edge node to the common port of the assistant edge node. If the assistant edge node receives the Fast-Edge-Hello packets from the common port before the Fast-Edge-Fail timer expires, the ring is in Health state. Otherwise, the ring transits to Disconnect state.

How RRPP works

Polling mechanism

The polling mechanism is used by the master node of an RRPP ring to examine the Health state of the ring network.

The master node sends Hello packets out of its primary port at the Hello interval. These Hello packets travel through each transit node on the ring in turn.

- If the ring is complete, the secondary port of the master node receives Hello packets before the Fail timer expires. The master node keeps the secondary port blocked.
- If the ring is disconnected, the secondary port of the master node fails to receive Hello packets before the Fail timer expires. The master node releases the secondary port from blocking protected VLANs. It sends Common-Flush-FDB packets to instruct all transit nodes to update their own MAC address entries and ARP/ND entries.

Load balancing

In a ring network, traffic from multiple VLANs might be transmitted at the same time. RRPP can implement load balancing by transmitting traffic from different VLANs along different paths.

You can configure multiple RRPP domains for a ring network. Each RRPP domain transmits the traffic from the specified VLANs (protected VLANs). Traffic from different VLANs can be transmitted according to different topologies in the ring network for load balancing.

As shown in Figure 6, Ring 1 is configured as the primary ring of Domain 1 and Domain 2, which are configured with different protected VLANs. Device A is the master node of Ring 1 in Domain 1. Device B is the master node of Ring 1 in Domain 2. With such configurations, traffic from different VLANs can be transmitted on different links for load balancing in the single-ring network.

Link down alarm mechanism

In an RRPP domain, when the transit node, edge node, or assistant edge node finds that any of its ports is down, it immediately sends Link-Down packets to the master node. When the master node receives a Link-Down packet, it takes the following actions:

- Releases the secondary port from blocking protected VLANs.
- Sends Common-Flush-FDB packets to instruct all the transit nodes, edge nodes, and assistant edge nodes to update their MAC address entries and ARP/ND entries.

After each node updates its own entries, traffic is switched to the normal link.

Ring recovery

When the ports in an RRPP domain on the transit nodes, edge nodes, or assistant edge nodes come up again, the ring is recovered. However, the master node might detect the ring recovery after a period of time. A temporary loop might arise in the protected VLAN during this period. As a result, a broadcast storm occurs.

To prevent such cases, non-master nodes block the ports immediately when they find the ports accessing the ring are brought up again. The nodes block only the packets from the protected VLAN, and they permit only the packets from the control VLAN to pass through. The blocked ports are activated only when the nodes determine that no loop will be generated by these ports.

Broadcast storm suppression mechanism in case of SRPT failure in a multi-homed subring

As shown in Figure 5, Ring 1 is the primary ring, and Ring 2 and Ring 3 are subrings. When the two SRPTs between the edge node and the assistant edge node are down, the master nodes of Ring 2 and Ring 3 will open their secondary ports. A loop is generated among Device B, Device C, Device E, and Device F, causing a broadcast storm.

To avoid generating a loop, the edge node will temporarily block the edge port. The blocked edge port is activated only when the edge node determines that no loop will be generated when the edge port is activated.

RRPP ring group

In an edge node RRPP ring group, only the activated subring with the smallest domain ID and ring ID can send Edge-Hello packets. In an assistant edge node RRPP ring group, any activated subring that has received Edge-Hello packets will forward these packets to the other activated subrings. When an edge node RRPP ring group and an assistant edge node RRPP ring group are configured, the CPU workload is reduced because of the following reasons:

- Only one subring sends Edge-Hello packets on the edge node.
- Only one subring receives Edge-Hello packets on the assistant edge node.

As shown in Figure 5, Device B is the edge node of Ring 2 and Ring 3. Device C is the assistant edge node of Ring 2 and Ring 3. Device B and Device C need to send or receive Edge-Hello packets frequently. If more subrings are configured or more domains are configured for load balancing, Device B and Device C will send or receive a large number of Edge-Hello packets.

To reduce Edge-Hello traffic, perform the following tasks:

- Assign Ring 2 and Ring 3 to an RRPP ring group configured on the edge node Device B.
- Assign Ring 2 and Ring 3 to an RRPP ring group configured on the assistant edge node Device C.

If all rings are activated, only Ring 2 on Device B sends Edge-Hello packets.

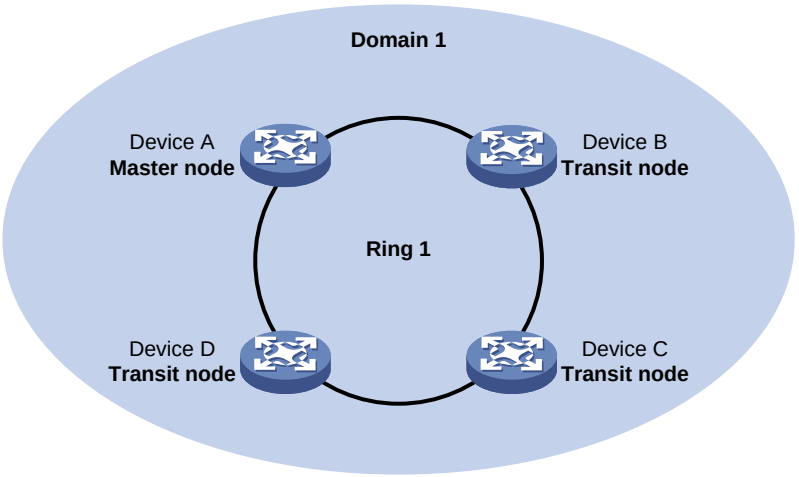
Fast detection mechanism

Ideally, an RRPP ring can fast converge because its transit nodes can detect link failures quickly and send out notifications immediately. In practice, some devices on an RRPP ring might not support RRPP. RRPP can detect link failures between these devices only through the timeout mechanism. This results in long-time traffic interruption and failure to implement millisecond-level convergence.

To address this problem, a fast detection mechanism was introduced. The mechanism works as follows:

- The master node sends Fast-Hello packets out of its primary port at the interval specified by the Fast-Hello timer. If the secondary port receives the Fast-Hello packets sent by the local master node before the Fast-Fail timer expires, the entire ring is in Health state. Otherwise, the ring transits to Disconnect state.
- The edge node sends Fast-Edge-Hello packets out of its common ports at the interval specified by the timer resolution. If the assistant edge node fails to receive the Fast-Edge-Hello packets within three times the timer resolution, the SRPTs transit to Disconnect state.

As shown in Figure 2, when fast detection is enabled for RRPP domain 1, Device A (master node of Ring 1) sends Fast-Hello packets periodically. It determines the ring status according to whether Fast-Hello packets are received before the Fast-Fail timer expires, implementing link status fast detection.



To implement fast detection on an RRPP ring, enable fast detection on the master node, edge node, and assistant edge node of the RRPP ring.

Typical RRPP networking

Single ring

As shown in Figure 2, only a single ring exists in the network topology. You need only define an RRPP domain.

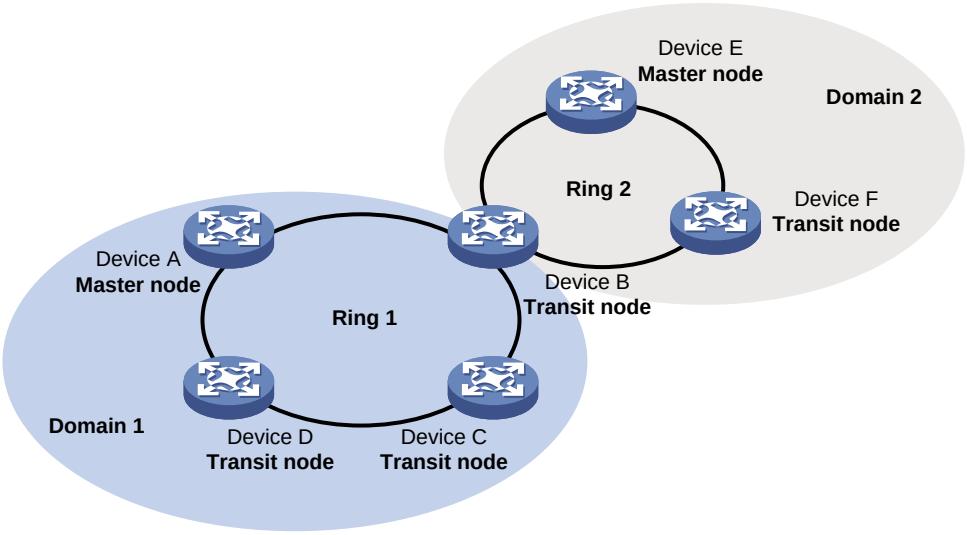


Figure 2 Schematic diagram for a single-ring network

Tangent rings

As shown in Figure 3, two or more rings exist in the network topology and only one common node exists between rings. You must define an RRPP domain for each ring.

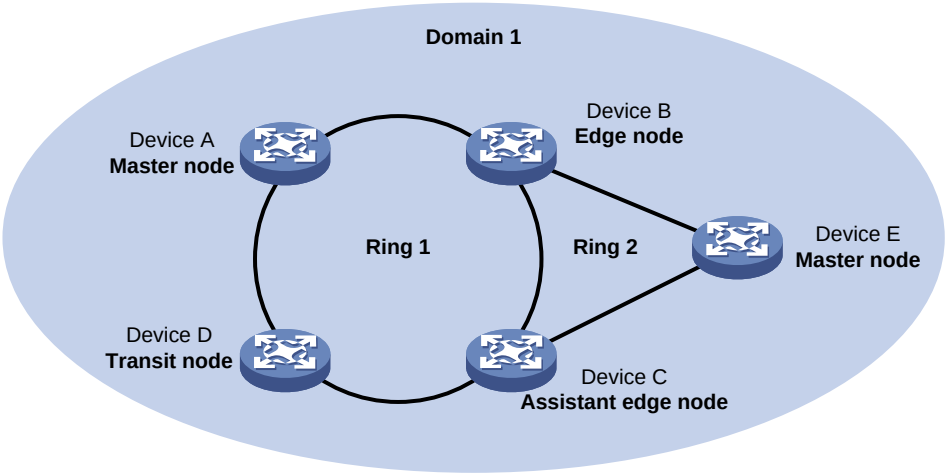

Figure 3 Schematic diagram for a tangent-ring network

Intersecting rings

As shown in Figure 4, two or more rings exist in the network topology and two common nodes exist between rings. You need only define an RRPP domain and configure one ring as the primary ring and the other rings as subrings.

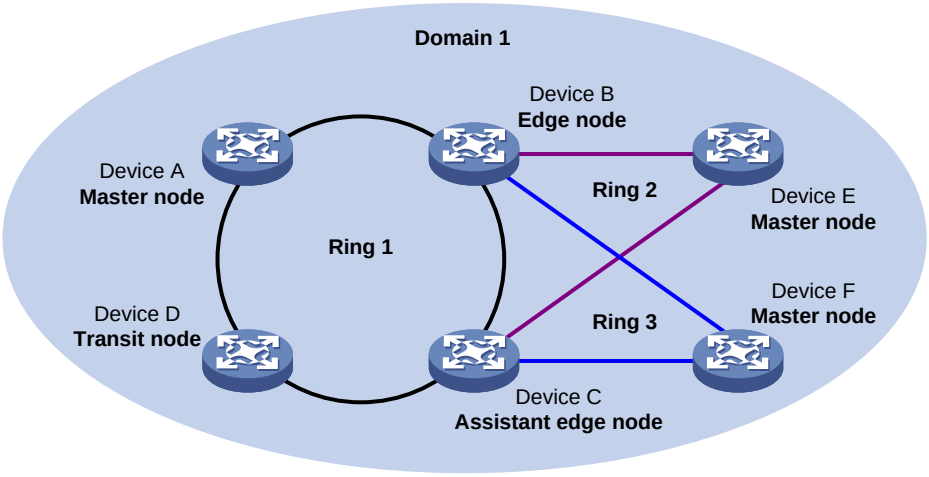

Figure 4 Schematic diagram for an intersecting-ring network

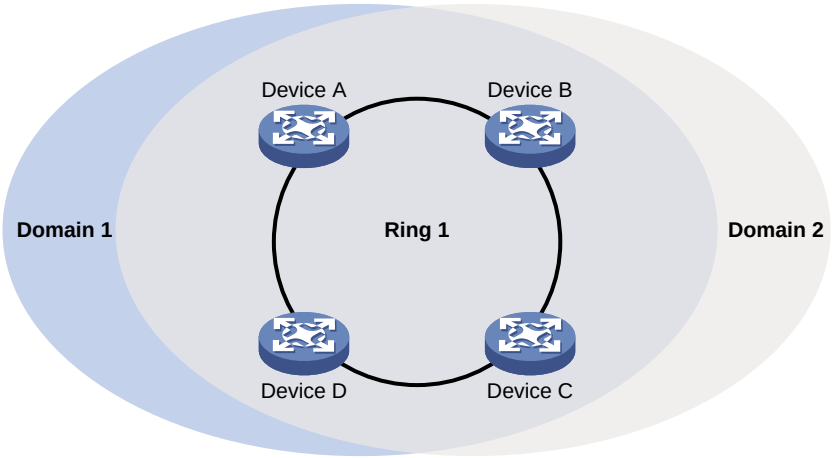
Dual-homed rings

As shown in Figure 5, two or more rings exist in the network topology and two similar common nodes exist between rings. You need only define an RRPP domain and configure one ring as the primary ring and the other rings as subrings.

Figure 5 Schematic diagram for a dual-homed-ring network

Single-ring load balancing



In a single-ring network, you can achieve load balancing by configuring multiple domains.

As shown in Figure 6:

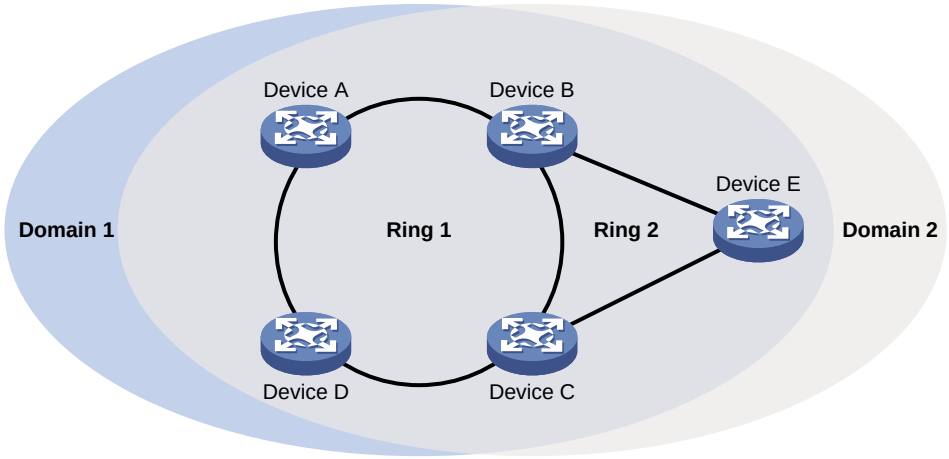
- Ring 1 is configured as the primary ring of both Domain 1 and Domain 2.
- Domain 1 and Domain 2 are configured with different protected VLANs.
- In Domain 1, Device A is configured as the master node of Ring 1.
- In Domain 2, Device B is configured as the master node of Ring 1.

Such configurations enable the ring to block different links based on VLANs and achieve single-ring load balancing.

Figure 6 Schematic diagram for a single-ring load balancing network

Intersecting-ring load balancing

In an intersecting-ring network, you can also achieve load balancing by configuring multiple domains.



As shown in Figure 7:

- Ring 1 is the primary ring and Ring 2 is the subring in both Domain 1 and Domain 2.
- Domain 1 and Domain 2 are configured with different protected VLANs.
- Device A is configured as the master node of Ring 1 in Domain 1.

- Device D is configured as the master node of Ring 1 in Domain 2.
- Device E is configured as the master node of Ring 2 in both Domain 1 and Domain 2. However, different ports on Device E are blocked in Domain 1 and Domain 2.

Traffic from different VLANs can travel over different paths in the subring and primary ring.

Figure 7 Schematic diagram for an intersecting-ring load balancing network

Protocols and standards

RFC 3619, *Extreme Networks' Ethernet Automatic Protection Switching (EAPS) Version 1*

Restrictions and guidelines: RRPP configuration

- RRPP does not have an auto election mechanism. You must configure each node in the ring network correctly for RRPP to monitor and protect the ring network.
- You can configure RRPP in the following order:
  - Create RRPP domains based on service planning.
  - Specify control VLANs and protected VLANs for each RRPP domain.
  - Determine the ring roles and node roles based on the traffic paths in each RRPP domain.

RRPP tasks at a glance

To configure RRPP, perform the following tasks:

1. Creating an RRPP domain

   Perform this task on devices you want to configure as nodes in the RRPP domain.
2. Configuring control VLANs

   Perform this task on all nodes in the RRPP domain.
3. Configuring protected VLANs

   Perform this task on all nodes in the RRPP domain.
4. Configuring RRPP rings
   a. Configuring RRPP ports

      Perform this task on each node's ports intended for accessing RRPP rings.
   b. Configuring RRPP nodes

Perform this task on all nodes in the RRPP domain.

5. Activating an RRPP domain

   Perform this task on all nodes in the RRPP domain.

6. (Optional.) Configuring RRPP timers

   Perform this task on the master node in the RRPP domain.

   - Configuring the Hello timer and Fail timer
   - Configuring the link-up delay timer

7. (Optional.) Configuring RRPP fast detection

   a. Enabling fast detection

      Perform this task on the master node, edge node, and assistant edge node in the RRPP domain.

   b. Configuring fast detection timers

      Perform this task on the master node in the RRPP domain.

8. (Optional.) Configuring an RRPP ring group

   Perform this task on the edge node and assistant edge node in the RRPP domain.

9. (Optional.) Enabling SNMP notifications for RRPP

Prerequisites for RRPP

Before you configure RRPP, you must physically construct a ring-shaped Ethernet topology.

Creating an RRPP domain

About this task

When you create an RRPP domain, specify a domain ID to uniquely identify the RRPP domain. All devices in the same RRPP domain must be configured with the same domain ID.

Restrictions and guidelines

Perform this task on devices you want to configure as nodes in the RRPP domain.

Procedure

1. Enter system view.

   `system-view`

2. Create an RRPP domain and enter RRPP domain view.

   `rrpp domain` *`domain-id`*

Configuring control VLANs

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you configure RRPP rings in an RRPP domain, configure the same control VLANs for all nodes in the RRPP domain first. You need only configure the primary control VLAN for an RRPP domain. The system automatically configures the secondary control VLAN. It uses the primary control VLAN ID plus 1 as the secondary control VLAN ID. For the control VLAN configuration to succeed, make sure the IDs of the two control VLANs are consecutive and have not been previously assigned.
- Do not configure the default VLAN of a port accessing an RRPP ring as the control VLAN.

- For RRPPDUs to be correctly forwarded, do not enable QinQ or VLAN mapping on control VLANs.
- After you configure RRPP rings for an RRPP domain, you cannot delete or modify the primary control VLAN of the domain. You can only use the **undo control-vlan** command to delete a primary control VLAN.
- To transparently transmit RRPPDUs on a device not configured with RRPP, make sure only the two ports accessing the RRPP ring permit packets from the control VLANs. Otherwise, the packets from other VLANs might enter the control VLANs in transparent transmission mode and strike the RRPP ring.

Procedure

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*
3. Configure the primary control VLAN for the RRPP domain.
   control-vlan *vlan-id*

Configuring protected VLANs

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you configure RRPP rings in an RRPP domain, configure the same protected VLANs for all nodes in the RRPP domain. All VLANs to which the RRPP ports are assigned must be protected by the RRPP domains.
- When you configure load balancing, you must configure different protected VLANs for different RRPP domains.

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*
3. Configure protected VLANs for the RRPP domain.
   protected-vlan reference-instance *instance-id-list*

Configuring RRPP rings

When you configure an RRPP ring, you must configure the ports connecting each node to the RRPP ring before configuring the nodes.

Prerequisites

Before you configure an RRPP ring, you must configure control VLANs and protected VLANs.

Configuring RRPP ports

Restrictions and guidelines

- Perform this task on each node's ports intended for accessing RRPP rings.
- Do not enable the OAM remote loopback function on an RRPP port. Otherwise, temporary broadcast storms might occur.
- To accelerate topology convergence, use the **link-delay** command to enable link status rapid report function on an RRPP port. Use this command to set the physical state change suppression interval to 0 seconds. For more information about the **link-delay** command, see *Interface Command Reference*.
- Do not assign a port to both an aggregation group and an RRPP ring. If you do so, the port does not take effect on the RRPP ring.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure the link type of the interface as trunk.
   port link-type trunk
   By default, the link type of an interface is access.
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.
4. Assign the trunk port to the protected VLANs of the RRPP domain.
   port trunk permit vlan { *vlan-id-list* | **all** }
   By default, a trunk port allows only packets from VLAN 1 to pass through.
   RRPP ports always allow packets from the control VLANs to pass through.
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.
5. Disable the spanning tree feature.
   undo stp enable
   By default, the spanning tree feature is enabled.
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.

Configuring RRPP nodes

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- If a device carries multiple RRPP rings in an RRPP domain, it can only be an edge node or an assistant edge node on a subring.
- When you configure an edge node or an assistant edge node, you must configure the primary ring before configuring the subrings.

Specifying a master node

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*

3. Specify the current device as the master node of the ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode master** [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

Specifying a transit node

1. Enter system view.

   system-view

2. Enter RRPP domain view.

   rrpp domain *domain-id*

3. Specify the current device as a transit node of the ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode transit** [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

Specifying an edge node

1. Enter system view.

   system-view

2. Enter RRPP domain view.

   rrpp domain *domain-id*

3. Specify the current device as a master node or transit node of the primary ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode** { **master** | **transit** } [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

4. Specify the current device as the edge node of a subring, and specify the edge port.

   ring *ring-id* **node-mode edge** [**edge-port** *interface-type interface-number*]

Specifying an assistant edge node

1. Enter system view.

   system-view

2. Enter RRPP domain view.

   rrpp domain *domain-id*

3. Specify the current device as a master node or transit node of the primary ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode** { **master** | **transit** } [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

   By default, a device is not a node of the RRPP ring.

4. Specify the current device as the assistant edge node of the subring, and specify an edge port.

   ring *ring-id* **node-mode assistant-edge** [**edge-port** *interface-type interface-number*]

Activating an RRPP domain

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you activate an RRPP domain on the current device, enable the RRPP protocol and RRPP rings for the RRPP domain on the current device.
- Before you enable subrings on a device, you must enable the primary ring. Before you disable the primary ring on the device, you must disable all subrings. Otherwise, the system displays error prompts.
- To prevent Hello packets of subrings from being looped on the primary ring, enable the primary ring on its master node first. Then enable the subrings on their respective master nodes.

Procedure

1. Enter system view.
   `system-view`
2. Enable RRPP.
   `rrpp enable`
   By default, RRPP is disabled.
3. Enter RRPP domain view.
   `rrpp domain` *`domain-id`*
4. Enable the specified RRPP ring.
   `ring` *`ring-id`* **`enable`**
   By default, an RRPP ring is disabled.

Configuring RRPP timers

Restrictions and guidelines for RRPP timer configuration

Perform this task on the master node of an RRPP domain.

Configuring the Hello timer and Fail timer

Restrictions and guidelines

- The Fail timer must be greater than or equal to three times the Hello timer.
- In a dual-homed-ring network, to avoid temporary loops when the primary ring fails, make sure the value of *A* is greater than the value of *B*, where:
  - *A* is the difference between the Fail timer values on the master node of the subring and the master node of the primary ring.
  - *B* is twice the Hello timer value on the master node of the subring.

Procedure

1. Enter system view.
   `system-view`
2. Enter RRPP domain view.
   `rrpp domain` *`domain-id`*
3. Set the Hello timer and Fail timer for the RRPP domain.

timer hello-timer *hello-value* **fail-timer** *fail-value*

By default, the Hello timer value is 1 second and the Fail timer value is 3 seconds.

Configuring the link-up delay timer

Restrictions and guidelines

If the **distribute** keyword is not specified, the link-up delay timer value cannot be greater than the Fail timer value minus twice the Hello timer value.

If you specify the **distribute** keyword in an RRPP network implementing load balancing, you must configure the link-up delay timer for each RRPP domain for the timer to take effect. If you set different timer values for different RRPP domains, the smallest timer value takes effect.

Procedure

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Set the link-up delay timer for the RRPP domain.

   linkup-delay-timer *delay-time* [**distribute**]

   By default, the link-up delay timer value is 0 seconds, and the **distribute** keyword is not specified.

Configuring RRPP fast detection

Enabling fast detection

Restrictions and guidelines

- Perform this task on the master node, edge node, and assistant edge node in the RRPP domain.
- As a best practice, configure fast detection on the master node of a subring only when the edge node and assistant edge node of the subring support fast detection.
- When you configure fast detection in an RRPP domain, enable fast detection first on the edge node, and then on the assistant edge node. Otherwise, the assistant edge node might fail to receive Fast-Edge-Hello packets and consider the master node faulty even if it is not.

Procedure

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Enable fast detection.

   fast-detection enable

   By default, fast detection is disabled.

Configuring fast detection timers

Restrictions and guidelines

- Perform this task on the master node in the RRPP domain.
- The Fast-Fail timer must be equal to or greater than three times the Fast-Hello timer.
- When you configure the Fast-Hello timer, take the device capability into consideration. A small Fast-Hello timer value might cause the link to be unstable.
- In a dual-homed-ring network, to avoid temporary loops when the primary ring fails, make sure the following requirements are met:
  - The Fast-Fail timer value on the master node of the subring is equal to or greater than six times the timer resolution.
  - The difference between the Fast-Fail timer values on the master node of the subring and the master node of the primary ring is greater than twice the Fast-Hello timer value on the master node of the subring.

Procedure

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Set the Fast-Hello timer and Fast-Fail timer.

   fast-timer hello-timer *hello-value* **fail-timer** *fail-value*

   By default, the Fast-Hello timer is 20 milliseconds, and the Fast-Fail timer is 60 milliseconds.
4. Set the Fast-Edge-Hello timer and Fast-Edge-Fail timer.

   fast-edge-timer hello-timer *hello-value* **fail-timer** *fail-value*

   By default, the Fast-Edge-Hello timer is 10 milliseconds, and the Fast-Edge-Fail timer is 30 milliseconds.

Configuring an RRPP ring group

About this task

To reduce Edge-Hello traffic, assign subrings with the same edge node and assistant edge node to an RRPP ring group. An RRPP ring group must be configured on both the edge node and the assistant edge node. It can only be configured on these two types of nodes.

Restrictions and guidelines

- Perform this task on the edge node and assistant edge node in the RRPP domain.
- You can assign a subring to only one RRPP ring group. The RRPP ring groups configured on the edge node and the assistant edge node must contain the same subrings. Otherwise, the RRPP ring group cannot operate correctly.
- The subrings in an RRPP ring group must share the same edge node and assistant edge node. The edge node and the assistant edge node must have the same SRPTs.
- Make sure a device is either the edge node or the assistant edge node on the subrings in an RRPP ring group.
- Make sure the RRPP ring groups on the edge node and the assistant edge node have the same configurations and activation status.
- Make sure all subrings in an RRPP ring group have the same SRPTs. If the SRPTs of these subrings are different, the RRPP ring group cannot operate correctly.

Procedure

1. Enter system view.
   system-view
2. Create an RRPP ring group and enter RRPP ring group view.
   rrpp ring-group *ring-group-id*
   By default, no RRPP ring groups exist.
3. Assign the specified subrings to the RRPP ring group.
   domain *domain-id* **ring** *ring-id-list*
   By default, no subrings are assigned to an RRPP ring group.

Enabling SNMP notifications for RRPP

About this task

To report critical RRPP events to an NMS, enable SNMP notifications for RRPP. For RRPP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

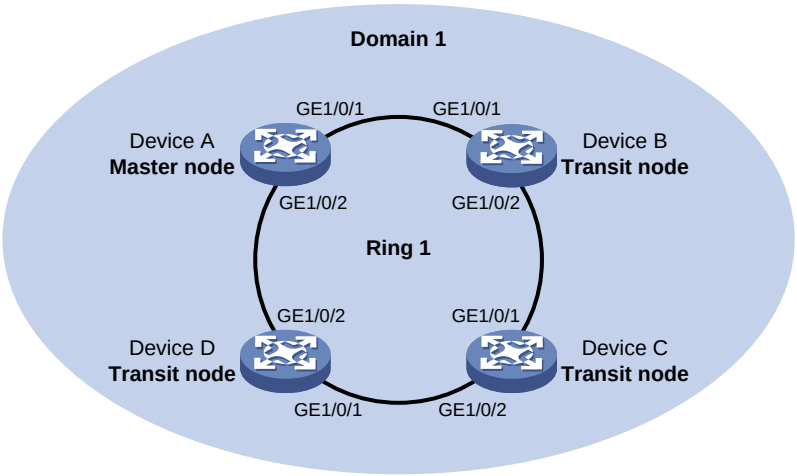
1. Enter system view.
   system-view
2. Enable SNMP notifications for RRPP.
   snmp-agent trap enable rrpp [**major-fault** | **multi-master** | **ring-fail** | **ring-recover**] *
   By default, SNMP notifications for RRPP are disabled.

Display and maintenance commands for RRPP

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display brief RRPP information.	**display rrpp brief**
Display RRPP group configuration information.	**display rrpp ring-group** [*ring-group-id*]
Display RRPPDU statistics.	**display rrpp statistics domain** *domain-id* [**ring** *ring-id*]
Display detailed RRPP information.	**display rrpp verbose domain** *domain-id* [**ring** *ring-id*]
Clear RRPPDU statistics.	**reset rrpp statistics domain** *domain-id* [**ring** *ring-id*]

RRPP configuration examples



Example: Configuring a single ring

Network configuration

As shown in Figure 8:

- Device A, Device B, Device C, and Device D form RRPP domain 1. Specify the primary control VLAN of RRPP domain 1 as VLAN 4092. Specify the protected VLANs of RRPP domain 1 as VLANs 1 through 30.
- Device A, Device B, Device C, and Device D form primary ring 1.
- Specify Device A as the master node of primary ring 1, GigabitEthernet 1/0/1 as the primary port, and GigabitEthernet 1/0/2 as the secondary port.
- Specify Device B, Device C, and Device D as the transit nodes of primary ring 1. Specify GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port on Device B, Device C, and Device D.

Figure 8 Network diagram

Procedure

1. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceB] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device B as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
[DeviceB-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

   Configure Device C in the same way Device B is configured.

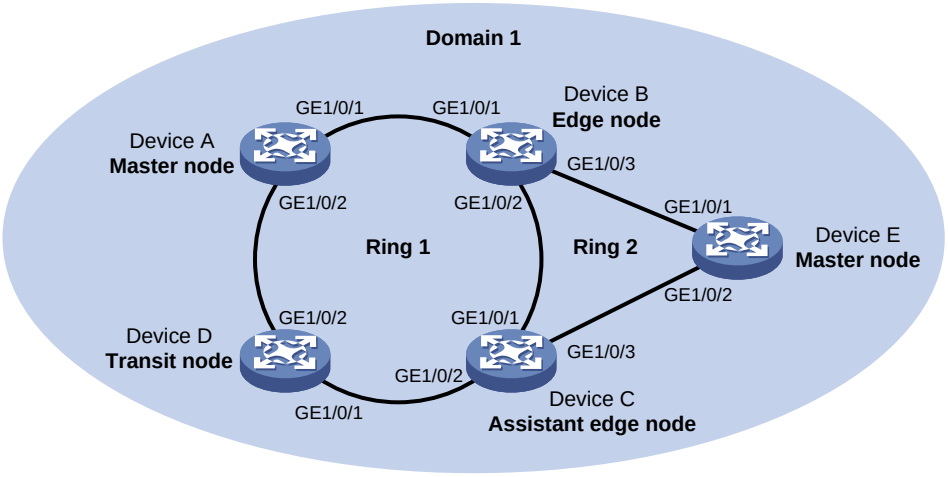
4. Configure Device D:

   Configure Device D in the same way Device B is configured.

Verifying the configuration

Use the **display** commands to view RRPP configuration and operational information on each device.

Example: Configuring intersecting rings



Network configuration

As shown in Figure 9:

- Device A, Device B, Device C, Device D, and Device E form RRPP domain 1. VLAN 4092 is the primary control VLAN of RRPP domain 1. RRPP domain 1 protects VLANs 1 through 30.
- Device A, Device B, Device C, and Device D form primary ring 1. Device B, Device C, and Device E form subring 2.
- Device A is the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.
- Device E is the master node of subring 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.
- Device B is the transit node of primary ring 1 and the edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port.

- Device C is the transit node of primary ring 1 and the assistant edge node of subring 1, with GigabitEthernet 1/0/3 as the edge port.
- Device D is the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.

Figure 9 Network diagram

Procedure

1. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
```

```
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/3
```

```
[DeviceB-GigabitEthernet1/0/3] link-delay up 0
[DeviceB-GigabitEthernet1/0/3] undo stp enable
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/3] quit
```

Create RRPP domain 1.

```
[DeviceB] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device B as a transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
```

Configure Device B as the edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port. Enable ring 2.

```
[DeviceB-rrpp-domain1] ring 2 node-mode edge edge-port gigabitethernet 1/0/3
[DeviceB-rrpp-domain1] ring 2 enable
[DeviceB-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
```

```
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/3
[DeviceC-GigabitEthernet1/0/3] link-delay up 0
[DeviceC-GigabitEthernet1/0/3] link-delay down 0
[DeviceC-GigabitEthernet1/0/3] undo stp enable
[DeviceC-GigabitEthernet1/0/3] port link-type trunk
[DeviceC-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/3] quit
```

Create RRPP domain 1.

```
[DeviceC] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceC-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceC-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device C as a transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceC-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceC-rrpp-domain1] ring 1 enable
```

Configure Device C as the assistant edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port. Enable ring 2.

```
[DeviceC-rrpp-domain1] ring 2 node-mode assistant-edge edge-port gigabitethernet
1/0/3
[DeviceC-rrpp-domain1] ring 2 enable
[DeviceC-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceC] rrpp enable
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceD] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device D as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceD] rrpp enable
```

5. Configure Device E:

Create VLANs 1 through 30.

```
<DeviceE> system-view
[DeviceE] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] link-delay up 0
[DeviceE-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

```
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] link-delay up 0
[DeviceE-GigabitEthernet1/0/2] link-delay down 0
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceE] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceE-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceE-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device E as the master node of subring 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 2.

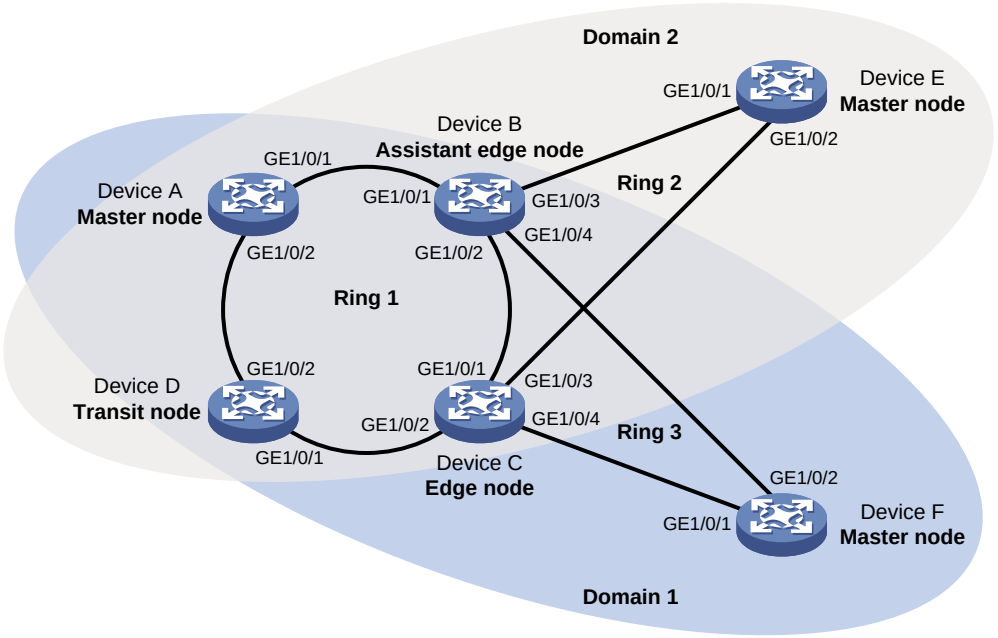
```
[DeviceE-rrpp-domain1] ring 2 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 1
[DeviceE-rrpp-domain1] ring 2 enable
[DeviceE-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceE] rrpp enable
```

Verifying the configuration

Use the **display** commands to view RRPP configuration and operational information on each device.



Example: Configuring load-balanced intersecting rings

Network configuration

As shown in Figure 10:

- Device A, Device B, Device C, Device D, and Device F form RRPP domain 1. VLAN 100 is the primary control VLAN of the RRPP domain. Device A is the master node of the primary ring, Ring 1. Device D is the transit node of Ring 1. Device F is the master node of the subring Ring 3. Device C is the edge node of the subring Ring 3. Device B is the assistant edge node of the subring Ring 3.
- Device A, Device B, Device C, Device D, and Device E form RRPP domain 2. VLAN 105 is the primary control VLAN of the RRPP domain. Device A is the master node of the primary ring, Ring 1. Device D is the transit node of Ring 1. Device E is the master node of the subring Ring 2. Device C is the edge node of the subring Ring 2. Device B is the assistant edge node of the subring Ring 2.
- Specify VLAN 11 as the protected VLAN of domain 1, and VLAN 12 the protected VLAN of domain 2. You can implement VLAN-based load balancing on Ring 1.
- Ring 2 and Ring 3 have the same edge node and assistant edge node, and the two subrings have the same SRPTs. You can add Ring 2 and Ring 3 to an RRPP ring group to reduce Edge-Hello traffic.

Figure 10 Network diagram

Procedure

1. Configure Device A:

   # Create VLANs 11 and 12.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 11 to 12
   ```

   # Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

   ```
   [DeviceA] stp region-configuration
   [DeviceA-mst-region] instance 1 vlan 11
   [DeviceA-mst-region] instance 2 vlan 12
   ```

   # Activate the MST region configuration.

   ```
   [DeviceA-mst-region] active region-configuration
   [DeviceA-mst-region] quit
   ```

   # Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] link-delay up 0
   [DeviceA-GigabitEthernet1/0/1] link-delay down 0
   ```

   # Disable the spanning tree feature on the port.

   ```
   [DeviceA-GigabitEthernet1/0/1] undo stp enable
   ```

   # Configure the port as a trunk port.

   ```
   [DeviceA-GigabitEthernet1/0/1] port link-type trunk
   ```

   # Remove the port from VLAN 1, and assign it to VLANs 11 and 12.

   ```
   [DeviceA-GigabitEthernet1/0/1] undo port trunk permit vlan 1
   [DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 11 12
   ```

   # Configure VLAN 11 as the default VLAN.

   ```
   [DeviceA-GigabitEthernet1/0/1] port trunk pvid vlan 11
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   ```

```
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceA-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceA] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceA-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceA-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/2 as the master port and GigabitEthernet 1/0/1 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain2] ring 1 node-mode master primary-port gigabitethernet 1/0/2
secondary-port gigabitethernet 1/0/1 level 0
[DeviceA-rrpp-domain2] ring 1 enable
[DeviceA-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 11 and 12.

```
<DeviceB> system-view
[DeviceB] vlan 11 to 12
```

Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 11
[DeviceB-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
```

```
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```
Disable the spanning tree feature on the port.
```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```
Configure the port as a trunk port.
```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```
Remove the port from VLAN 1, and assign it to VLANs 11 and 12.
```
[DeviceB-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 11 12
```
Configure VLAN 11 as the default VLAN.
```
[DeviceB-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceB-GigabitEthernet1/0/1] quit
```
Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.
```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceB-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceB-GigabitEthernet1/0/2] quit
```
Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/3.
```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] link-delay up 0
[DeviceB-GigabitEthernet1/0/3] link-delay down 0
```
Disable the spanning tree feature on the port.
```
[DeviceB-GigabitEthernet1/0/3] undo stp enable
```
Configure the port as a trunk port.
```
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
```
Remove the port from VLAN 1, and assign it to VLAN 12.
```
[DeviceB-GigabitEthernet1/0/3] undo port trunk permit vlan 1
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 12
```
Configure VLAN 12 as the default VLAN.
```
[DeviceB-GigabitEthernet1/0/3] port trunk pvid vlan 12
[DeviceB-GigabitEthernet1/0/3] quit
```
Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/4.
```
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] link-delay up 0
[DeviceB-GigabitEthernet1/0/4] link-delay down 0
```
Disable the spanning tree feature on the port.
```
[DeviceB-GigabitEthernet1/0/4] undo stp enable
```
Configure the port as a trunk port.
```
[DeviceB-GigabitEthernet1/0/4] port link-type trunk
```
Remove the port from VLAN 1, and assign it to VLAN 11.
```
[DeviceB-GigabitEthernet1/0/4] undo port trunk permit vlan 1
[DeviceB-GigabitEthernet1/0/4] port trunk permit vlan 11
```
Configure VLAN 11 as the default VLAN.

```
[DeviceB-GigabitEthernet1/0/4] port trunk pvid vlan 11
[DeviceB-GigabitEthernet1/0/4] quit
```

Create RRPP domain 1.

```
[DeviceB] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device B as a transit node of primary ring 1 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
```

Configure Device B as the assistant edge node of subring 3 in RRPP domain 1, with GigabitEthernet 1/0/4 as the edge port. Enable subring 3.

```
[DeviceB-rrpp-domain1] ring 3 node-mode assistant-edge edge-port gigabitethernet
1/0/4
[DeviceB-rrpp-domain1] ring 3 enable
[DeviceB-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceB] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceB-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceB-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device B as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain2] ring 1 enable
```

Configure Device B as the assistant edge node of subring 2 in RRPP domain 2, with GigabitEthernet 1/0/3 as the edge port. Enable subring 2.

```
[DeviceB-rrpp-domain2] ring 2 node-mode assistant-edge edge-port gigabitethernet
1/0/3
[DeviceB-rrpp-domain2] ring 2 enable
[DeviceC-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

Create VLANs 11 and 12.

```
<DeviceC> system-view
[DeviceC] vlan 11 to 12
```

Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 11
[DeviceC-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```
Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.
```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```
Disable the spanning tree feature on the port.
```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```
Configure the port as a trunk port.
```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```
Remove the port from VLAN 1, and assign it to VLANs 11 and 12.
```
[DeviceC-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 11 12
```
Configure VLAN 11 as the default VLAN.
```
[DeviceC-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceC-GigabitEthernet1/0/1] quit
```
Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.
```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceC-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceC-GigabitEthernet1/0/2] quit
```
Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/3.
```
[DeviceC] interface gigabitethernet 1/0/3
[DeviceC-GigabitEthernet1/0/3] link-delay up 0
[DeviceC-GigabitEthernet1/0/3] link-delay down 0
```
Disable the spanning tree feature on the port.
```
[DeviceC-GigabitEthernet1/0/3] undo stp enable
```
Configure the port as a trunk port.
```
[DeviceC-GigabitEthernet1/0/3] port link-type trunk
```
Remove the port from VLAN 1, and assign it to VLAN 12.
```
[DeviceC-GigabitEthernet1/0/3] undo port trunk permit vlan 1
[DeviceC-GigabitEthernet1/0/3] port trunk permit vlan 12
```
Configure VLAN 12 as the default VLAN.
```
[DeviceC-GigabitEthernet1/0/3] port trunk pvid vlan 12
[DeviceC-GigabitEthernet1/0/3] quit
```
Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/4.
```
[DeviceC] interface gigabitethernet 1/0/4
[DeviceC-GigabitEthernet1/0/4] link-delay up 0
[DeviceC-GigabitEthernet1/0/4] link-delay down 0
```
Disable the spanning tree feature on the port.
```
[DeviceC-GigabitEthernet1/0/4] undo stp enable
```
Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/4] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 11.

```
[DeviceC-GigabitEthernet1/0/4] undo port trunk permit vlan 1
[DeviceC-GigabitEthernet1/0/4] port trunk permit vlan 11
```

Configure VLAN 11 as the default VLAN.

```
[DeviceC-GigabitEthernet1/0/4] port trunk pvid vlan 11
[DeviceC-GigabitEthernet1/0/4] quit
```

Create RRPP domain 1.

```
[DeviceC] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceC-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceC-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device C as the transit node of primary ring 1 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceC-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceC-rrpp-domain1] ring 1 enable
```

Configure Device C as the edge node of subring 3 in RRPP domain 1, with GigabitEthernet 1/0/4 as the edge port. Enable subring 3.

```
[DeviceC-rrpp-domain1] ring 3 node-mode edge edge-port gigabitethernet 1/0/4
[DeviceC-rrpp-domain1] ring 3 enable
[DeviceC-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceC] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceC-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceC-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device C as the transit node of primary ring 1 in RRPP domain 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceC-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceC-rrpp-domain2] ring 1 enable
```

Configure Device C as the edge node of subring 2 in RRPP domain 2, with GigabitEthernet 1/0/3 as the edge port. Enable subring 2.

```
[DeviceC-rrpp-domain2] ring 2 node-mode edge edge-port gigabitethernet 1/0/3
[DeviceC-rrpp-domain2] ring 2 enable
[DeviceC-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceC] rrpp enable
```

4. Configure Device D:

Create VLANs 11 and 12.

```
<DeviceD> system-view
[DeviceD] vlan 11 to 12
```

Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 11
[DeviceD-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLANs 11 and 12.

```
[DeviceD-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 11 12
```

Configure VLAN 11 as the default VLAN.

```
[DeviceD-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceD-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceD-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceD] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device D as the transit node of primary ring 1 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceD] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceD-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceD-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device D as the transit node of primary ring 1 in RRPP domain 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain2] ring 1 enable
[DeviceD-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceD] rrpp enable
```

5. Configure Device E:

Create VLAN 12.

```
<DeviceE> system-view
[DeviceE] vlan 12
```

Map VLAN 12 to MSTI 2.

```
[DeviceE-vlan12] quit
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] link-delay up 0
[DeviceE-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 12.

```
[DeviceE-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 12
```

Configure VLAN 12 as the default VLAN.

```
[DeviceE-GigabitEthernet1/0/1] port trunk pvid vlan 12
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] link-delay up 0
[DeviceE-GigabitEthernet1/0/2] link-delay down 0
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 12
[DeviceE-GigabitEthernet1/0/2] port trunk pvid vlan 12
[DeviceE-GigabitEthernet1/0/2] quit
```

Create RRPP domain 2.

```
[DeviceE] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceE-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceE-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device E as the master mode of subring 2 in RRPP domain 2, with GigabitEthernet 1/0/2 as the primary port and GigabitEthernet 1/0/1 as the secondary port. Enable ring 2.

```
[DeviceE-rrpp-domain2] ring 2 node-mode master primary-port gigabitethernet 1/0/2
secondary-port gigabitethernet 1/0/1 level 1
[DeviceE-rrpp-domain2] ring 2 enable
[DeviceE-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceE] rrpp enable
```

6. Configure Device F:

Create VLAN 11.

```
<DeviceF> system-view
[DeviceF] vlan 11
[DeviceF-vlan11] quit
```

Map VLAN 11 to MSTI 1.

```
[DeviceF] stp region-configuration
[DeviceF-mst-region] instance 1 vlan 11
```

Activate the MST region configuration.

```
[DeviceF-mst-region] active region-configuration
[DeviceF-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceF] interface gigabitethernet 1/0/1
[DeviceF-GigabitEthernet1/0/1] link-delay up 0
[DeviceF-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceF-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceF-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 11.

```
[DeviceF-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceF-GigabitEthernet1/0/1] port trunk permit vlan 11
```

Configure VLAN 11 as the default VLAN.

```
[DeviceF-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceF-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceF] interface gigabitethernet 1/0/2
[DeviceF-GigabitEthernet1/0/2] link-delay up 0
[DeviceF-GigabitEthernet1/0/2] link-delay down 0
[DeviceF-GigabitEthernet1/0/2] undo stp enable
[DeviceF-GigabitEthernet1/0/2] port link-type trunk
[DeviceF-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceF-GigabitEthernet1/0/2] port trunk permit vlan 11
[DeviceF-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceF-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceF] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceF-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceF-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device F as the master node of subring 3 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable subring 3.

```
[DeviceF-rrpp-domain1] ring 3 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 1
[DeviceF-rrpp-domain1] ring 3 enable
[DeviceF-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceF] rrpp enable
```

7. Configure RRPP ring group settings on Device B and Device C:

Create RRPP ring group 1 on Device B, and add subrings 2 and 3 to the RRPP ring group.

```
[DeviceB] rrpp ring-group 1
[DeviceB-rrpp-ring-group1] domain 2 ring 2
[DeviceB-rrpp-ring-group1] domain 1 ring 3
```

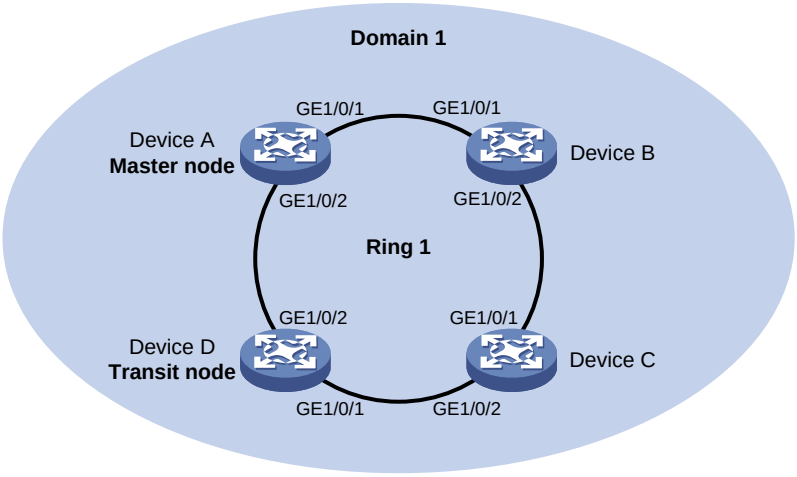
Create RRPP ring group 1 on Device C, and add subrings 2 and 3 to the RRPP ring group.

```
[DeviceC] rrpp ring-group 1
[DeviceC-rrpp-ring-group1] domain 2 ring 2
[DeviceC-rrpp-ring-group1] domain 1 ring 3
```

Verifying the configuration

Use the **display** commands to view RRPP configuration and operational information on each device.

Example: Configuring fast detection



Network configuration

As shown in Figure 11:

- Device A, Device B, Device C, and Device D form RRPP domain 1. VLAN 4092 is the primary control VLAN of RRPP domain 1. RRPP domain 1 protects VLANs 1 through 30.
- Device A is the master node and supports RRPP fast detection, providing a timer resolution of 10 milliseconds. The default Fast-Fail and Fast-Hello timers are 60 milliseconds and 20 milliseconds, respectively. Device D is a transit node. Device B and Device C do not support RRPP.

Neither Device B nor Device C supports RRPP. When the link between them fails, the link failure cannot be detected by the master node in a timely manner. Configure RRPP fast detection to implement fast link switchover even when the link between Device B and Device C fails.

Figure 11 Network diagram

Procedure

1. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of the primary ring Ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable Ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
```

Enable fast detection. Set the Fast-Hello timer and Fast-Fail timer to 100 milliseconds and 300 milliseconds, respectively.

```
[DeviceA-rrpp-domain1] fast-detection enable
[DeviceA-rrpp-domain1] fast-timer hello-timer 100 fail-timer 300
[DeviceA-rrpp-domain1] quit
```

Enable the RRPP protocol.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLAN 4092 and VLAN 4093.

```
<DeviceB> system-view
[DeviceB] vlan 4092 to 4093
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30, 4092, and 4093.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30 4092 4093
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30 4092 4093
```

3. Configure Device C:

Create VLAN 4092 and VLAN 4093.

```
<DeviceC> system-view
[DeviceC] vlan 4092 to 4093
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30, 4092, and 4093.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30 4092 4093
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30 4092 4093
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceD] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device D as a transit node of the primary ring Ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable Ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

Enable the RRPP protocol.

```
[DeviceD] rrpp enable
```

Verifying the configuration

Use the **display** commands to view RRPP configuration and operational information on Device A and Device D.

Troubleshooting RRPP

The primary node cannot receive Hello packets when the link state is normal

Symptom

When the link state is normal, the master node cannot receive Hello packets, and it unblocks the secondary port.

Analysis

The following are possible causes:

- One or more nodes on the RRPP ring are not enabled with RRPP.
- The domain IDs or control VLANs are not the same for all nodes on the RRPP ring.
- The port on the RRPP ring does not work correctly.

Solution

To resolve the problem:

1. Use the **display rrpp brief** command to determine whether RRPP is enabled for all nodes. If it is not, use the **rrpp enable** command and the **ring enable** command to enable RRPP and RRPP rings for all nodes.
2. Use the **display rrpp brief** command to determine whether the domain ID and primary control VLAN ID are the same for all nodes. If they are not, set the same domain ID and primary control VLAN ID for the nodes.
3. Use the **display rrpp verbose** command to examine the link state of each port in each ring.
4. Use the **debugging rrpp** command on each node to determine whether a port receives or transmits Hello packets. If it does not, Hello packets are lost.
5. If the problem persists, contact H3C Support.

Configuring ERPS

About ERPS

Ethernet Ring Protection Switching (ERPS) is a robust link layer protocol that ensures a loop-free topology and implements quick link recovery.

ERPS structure

Figure 1 ERPS ring structure

Rings

ERPS rings can be divided into major rings and subrings. An ERPS network consists of one major ring or multiple major rings, and multiple subrings. By default, a ring is a major ring. You can configure a ring as a subring manually.

As shown in Figure 1, a major ring is a closed ring formed by Device A, Device B, Device C, and Device D. A subring is an open ring formed by the link Device C<—>Device E<—>Device F<—>Device D.

RPL

An ERPS ring is composed of many nodes. Some nodes use ring protection links (RPLs) to prevent loops on the ERPS ring. As shown in Figure 1, the link between Device A and Device B and the link between Device E and Device F are RPLs.

Nodes

ERPS nodes include owner nodes, neighbor nodes, interconnection nodes, and normal nodes.

- The owner node and neighbor node block and unblock ports on the RPL to prevent loops and switch traffic. An RPL connects an owner node and a neighbor node.
- Interconnection nodes connect different rings. Interconnection nodes reside on subrings and forward service packets but not protocol packets.
- Normal nodes forward both service packets and protocol packets.

As shown in Figure 1, on the major ring, Device A is the owner node and Device B is the neighbor node. On the subring, Device E is the owner node and Device F is the neighbor node. Devices C and D are interconnection nodes.

Ports

Each node consists of two ERPS ring member ports: Port 0 and port 1. ERPS ring member ports have the following types:

- **RPL port**—Port on an RPL link.
- **Interconnection port**—Port that connects a subring to a major ring.
- **Normal port**—Default type of a port that forwards both service packets and protocol packets.

As shown in Figure 1, ports A1, B1, E1, and F1 are RPL ports. Ports C3 and D3 are interconnection ports. Other ports are normal ports.

Instances

An ERPS ring supports multiple ERPS instances. An ERPS instance is a logical ring to process service and protocol packets. Each ERPS instance has its own owner node and maintains its own state and data. An ERPS instance is uniquely identified by the ring ID and VLAN ID of ERPS packets. The ring ID indicates the ring of ERPS packets. It can be represented by the last byte in the destination MAC address of the packets. The VLAN ID indicates the ERPS instance of the packets.

ERPS protocol packets

ERPS protocol packets are Ring Automatic Protection Switching (R-APS) packets. You can configure the R-APS packet level. A node does not process R-APS packets whose levels are greater than the level of the packets sent by the node. On a ring, the levels of R-APS packets must be the same for all nodes in an ERPS instance.

Table 1 R-APS packet types and functions

Packet type	Function
No request, RPL block (NR-RB)	When the link is stable, an owner node in idle state periodically sends NR-RB packets to inform other nodes that the RPL ports are blocked. The nodes that receive the NR-RB packets unblock available ports and update MAC address entries.
No request (NR)	After the link fault is cleared, the node that detects the recovery periodically sends NR packets. When the owner node receives the NR packets, it starts the WTR timer. The node stops sending NR packets after receiving NR-RB packets from the owner node.
Signal fail (SF)	When a link fails to send or receive signals, the node that detects the fault periodically sends SF packets. When the owner node and neighbor node receive the FS packets, they unblock the RPL ports. The node stops sending SF packets after the fault is cleared.
Manual switch (MS)	A port configured with the MS mode is blocked and periodically sends MS packets. When other nodes receive the MS packets, they unblock available ports and update MAC address entries.
Forced switch (FS)	A port configured with the FS mode is blocked and periodically sends FS packets. When other nodes receive the FS packets, they unblock all ports and update MAC address entries.
Flush	If the topology of a subring changes, the interconnection ports on the subring broadcasts flush packets. All nodes that receive the flush packets update MAC address entries.

NOTE:

- Typically R-APS packets are transmitted within a ring. The flush packets sourced from the subring can be forwarded to the major ring.
- Service packets can be transmitted between different rings.

ERPS node states

Table 2 ERPS states

State	Description
Init	State for a non-interconnection node that has less than two ERPS ring member ports or for an interconnection node that does not have ERPS ring member ports.
Idle	Stable state when all non-RPL links are available. In this state, the owner node blocks the RPL port and periodically sends NR-RB packets. The neighbor node blocks the RPL port. All nodes enter the idle state after the owner node enters the idle state.
Protection	State when a non-RPL link is faulty. In this state, the RPL link is unblocked to forward traffic. All nodes enter the protection state after a node enters the protection state.
MS	State when traffic paths are manually switched. All nodes enter the MS state after a node is configured with the MS mode.
FS	State when traffic paths are forcibly switched. All nodes enter the FS state after a node is configured with the FS mode.
Pending	Transient state between the previous states.

ERPS timers

Hold-off timer

The hold-off timer starts when the port detects a link fault. The port reports the link fault if the fault persists when the timer expires.

This timer delays the fault report time and affects the link switching performance.

Guard timer

The guard timer starts when the port detects a link recovery. The port does not process R-APS packets before the timer expires.

This timer prevents R-APS packets from impacting the network and affects the link switching performance when multiple points of failures exist.

WTR timer

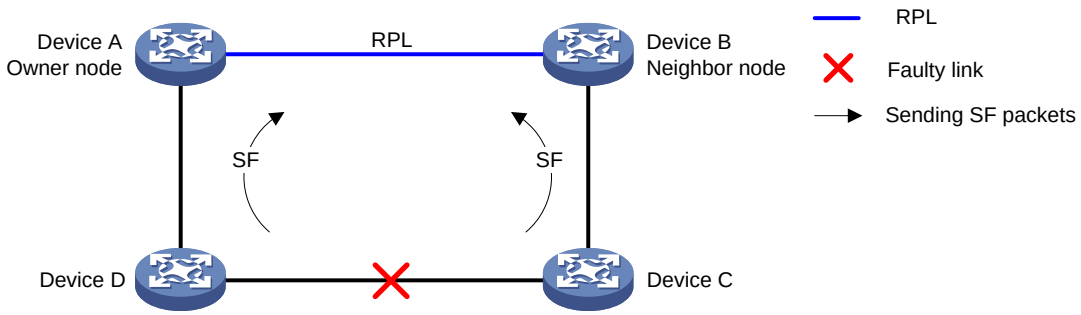
In revertive mode, the WTR timer starts when the owner node in protection state receives NR packets. The RPL is unblocked and the recovered node is blocked before the timer expires. The owner node blocks the RPL and sends NR-RB packets when the timer expires. If the port receives SF packets before the timer expires, the timer stops and the RPL remains unblocked.

This timer prevents intermittent link failures from impacting the network.

WTB timer

In revertive mode, the WTB timer starts when the owner node in MS or FS state receives NR packets. The RPL is unblocked and the recovered node sends NR packets before the timer expires. The owner node blocks the RPL and sends NR-RB packets when the timer expires. If the port receives SF packets before the timer expires, the timer stops and the RPL remains unblocked.

This timer prevents the RPL ports from being blocked and unblocked frequently.



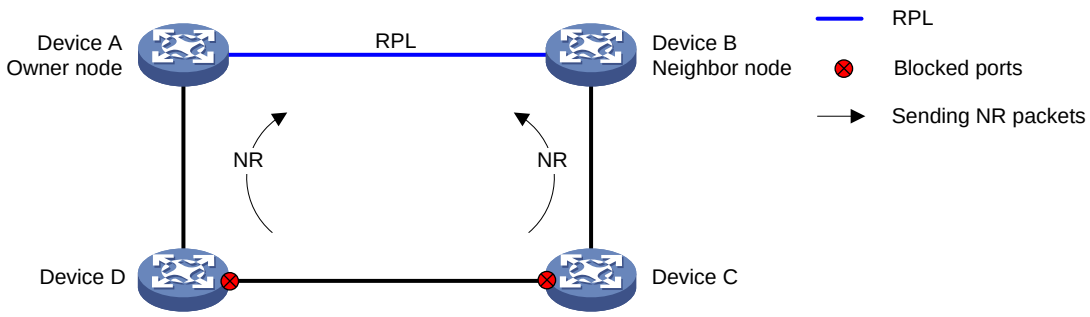
ERPS operation mechanism

ERPS uses the detection mechanism defined in ITU-T G.8032/Y.1344 to locate the point of failure and identify unidirectional or bidirectional faults.

ERPS uses the SF packets to report signal failures on a link and the NR packets to report link recovery. When a node detects a link status change, the node sends three packets first and then sends subsequent packets every five seconds.

Link-down report mechanism

Figure 2 Link-down report mechanism



As shown in Figure 2, the link-down report mechanism uses the following process:

1. Device C and Device D detect the link failure and perform the following operations:
   a. Block the ports on both side of the faulty link.
   b. Periodically send SF packets to other nodes.
2. Device A and Device B receive the SF packets and perform the following operations:
   a. Unblock RPL ports.
   b. Update the MAC address entries.

Service packets are switched to the RPL link.

Link recovery mechanism

Figure 3 Link recovery mechanism

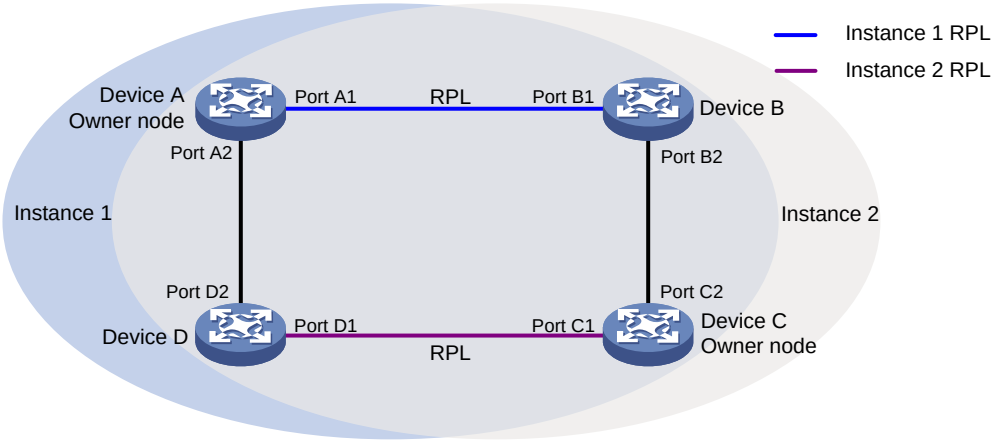
As shown in Figure 3, the link recovery mechanism uses the following process:

1. Device C and Device D detect the link recovery and perform the following operations:
   a. Block the recovered ports.
   b. Start the guard timer.
   c. Send NR packets.
2. When Device A (owner node) receives the NR packets, it does not perform any operations if it is in non-revertive mode. If Device A is in revertive mode, it performs the following operations:

a. Starts the WTR timer.

b. Blocks the RPL port and periodically sends NR-RB packets when the WTR timer expires.

3. When other nodes receive the NR-RB packets, they perform the following operations:



a. Device B (neighbor port) blocks the RPL port.

b. Device C and Device D unblock the recovered ports.

Service packets are switched to the recovered link.

Multi-instance load balancing mechanism

Figure 4 Multi-instance load balancing mechanism

An ERPS ring topology might carry traffic from multiple VLANs. Traffic from different VLANs can be load balanced among different ERPS instances.

ERPS uses the following types of VLANs:

- **Control VLAN**—Carries ERPS protocol packets. Each ERPS instance has its own control VLAN.
- **Protected VLAN**—Carries data packets. Each ERPS instance has its own protected VLAN. Protected VLANs are configured by using the mappings between VLANs and MSTIs.

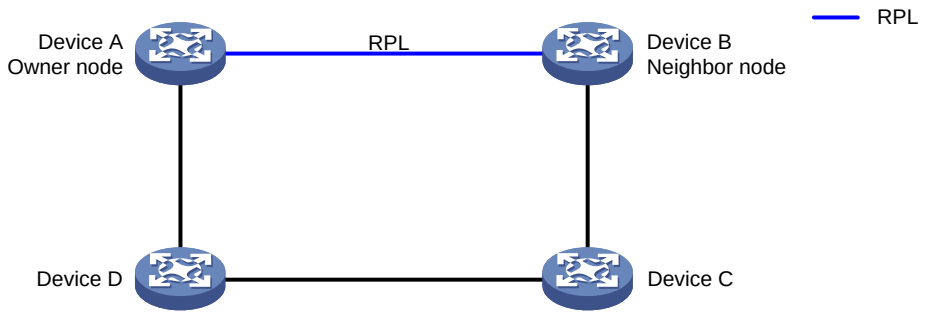
As shown in Figure 4, the ERPS ring is configured with instance 1 and instance 2. For instance 1, the owner node is Device A, and the RPL is the link between Device A and Device B. For instance 2, the owner node is Device C, and the RPL is the link between Device C and Device D. Traffic from different VLANs can be load balanced among different links.

Manual configuration mechanism

ERPS supports the following manual configuration modes:

- **MS**—Use the **`erps switch manual`** command to block an ERPS ring member port. A port in MS mode is blocked and sends MS packets. The nodes that receive the MS packets unblock available ports. If the nodes in MS mode receive an SF packet, they unblock the blocked ports.
- **FS**—Use the **`erps switch force ring`** command to block an ERPS ring member port. A port in FS mode is blocked and sends FS packets. The nodes that receive the FS packets unblock available ports. If the nodes in FS mode receive an SF packet, they do not unblock the blocked ports.

Collaboration mechanism



To detect and clear link faults typically for a fiber link, use ERPS with CFD and Track. You can associate ERPS ring member ports with the continuity check function of CFD through track entries. For more information about CFD and Track, see "Configuring CFD" and "Configuring Track."

ERPS network diagrams

One major ring

The network has one major ring.

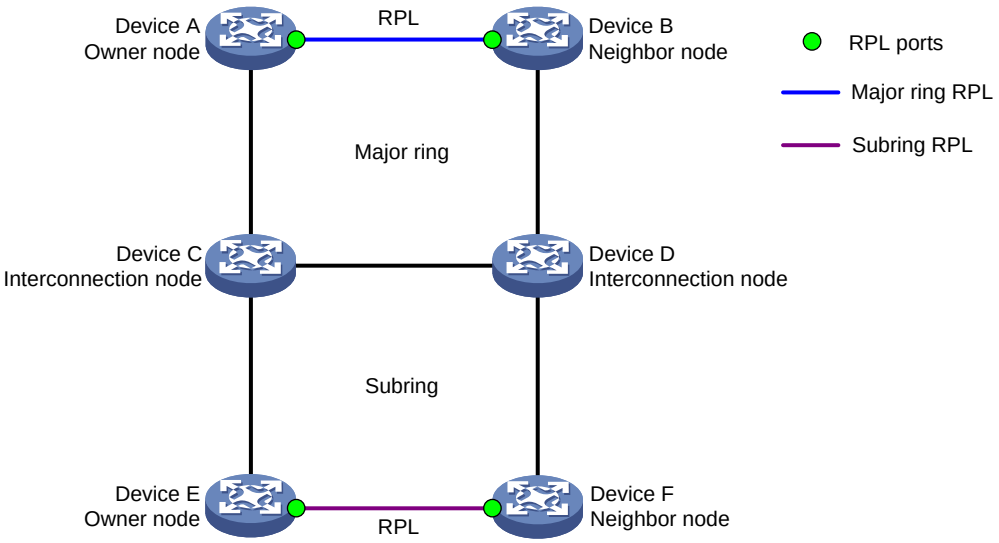


Figure 5 Network diagram

One major ring connecting one subring

The network has one major ring and one subring.

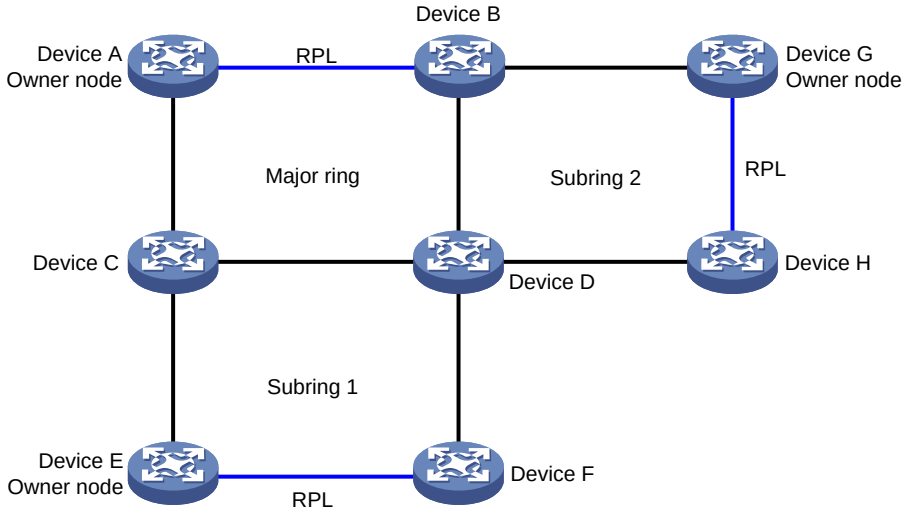

Figure 6 Network diagram

One major ring connecting multiple subrings

The network has three or more rings. Each subring is connected to the major ring by two interconnection nodes.

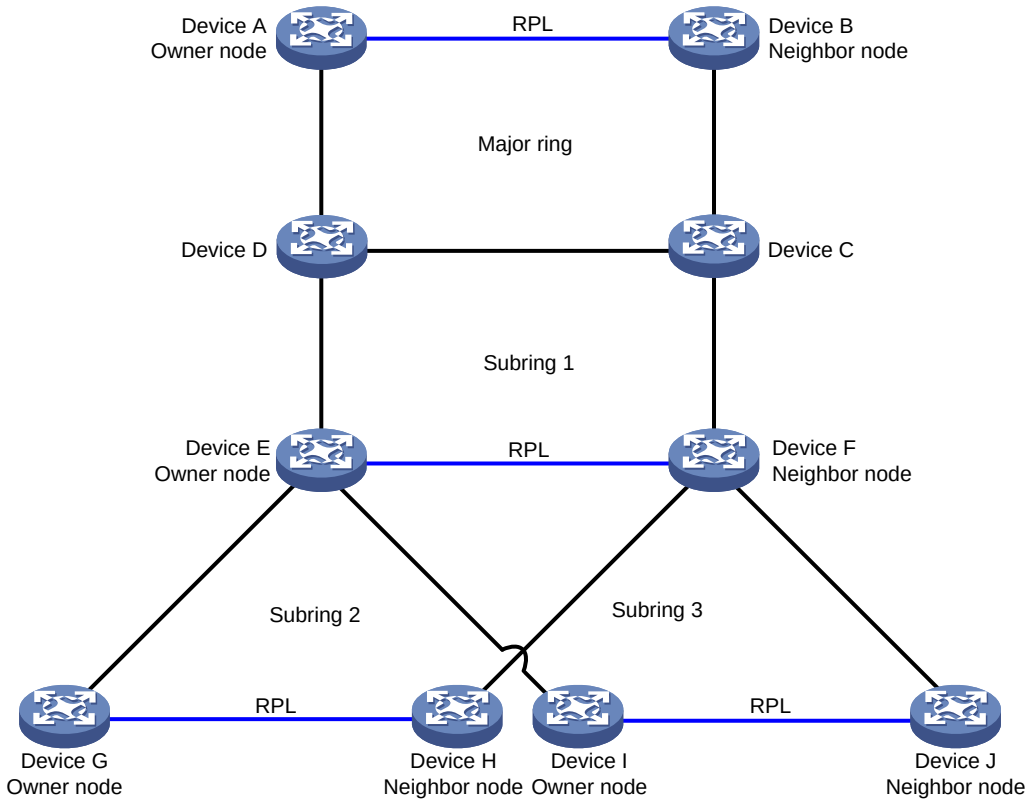

Figure 7 Network diagram

One subring connecting multiple subrings

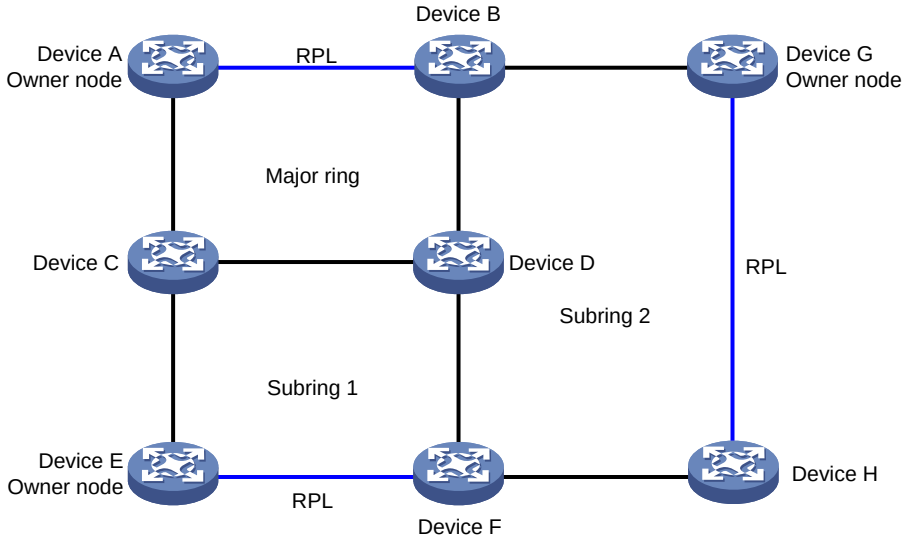
The network has three or more rings. As shown in Figure 8, subring 1 is connected to the major ring. Other subrings are connected to subring 1 by two interconnection nodes.

Figure 8 Network diagram

One subring connecting multiple rings

The network has three or more rings. A minimum of one subring is connected to two rings. As shown in Figure 9, one interconnection node on subring 2 is connected to the major ring; and another interconnection node is connected to subring 1. As shown in Figure 10, subring 3 is connected to subring 1 and subring 2.

Figure 9 Network diagram 1



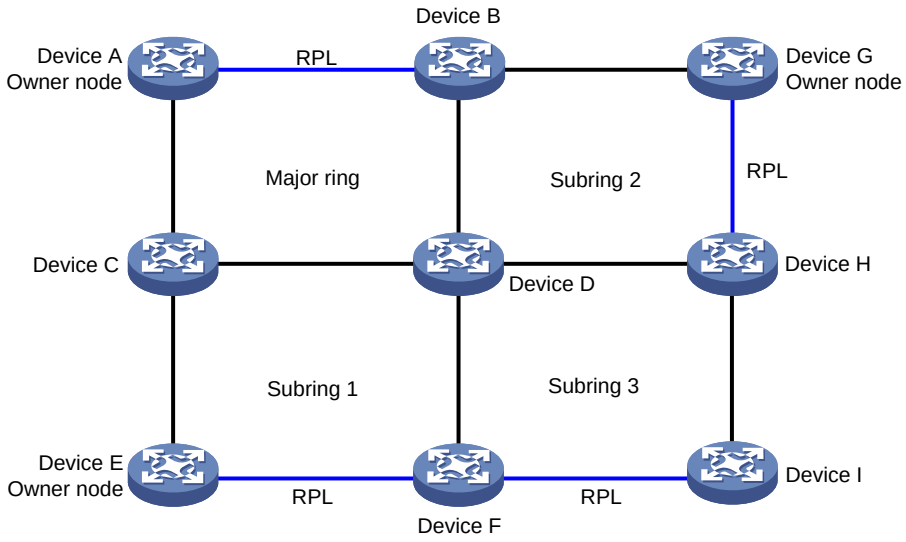


Figure 10 Network diagram 2

Protocols and standards

- ITU-T G.8032, *Recommendation ITU-T G.8032/Y.1344, Ethernet ring protection switching*
- IEEE 802.1D, *IEEE Std 802.1D™-2004, IEEE Standard for Local and Metropolitan Area Networks—Media Access Control (MAC) Bridges*
- IEEE 802.3, *IEEE Std 802.3-2008, IEEE Standard for Information technology*

Restrictions and guidelines: ERPS configuration

ERPS does not provide an election mechanism. To implement ring detection and protection, configure all nodes correctly.

ERPS tasks at a glance

To configure ERPS, perform the following tasks:

1. Enabling ERPS globally
   Perform this task on devices you want to configure as ERPS nodes.
2. Configuring an ERPS ring
   Perform this task on all nodes on an ERPS ring.
   a. Creating an ERPS ring
   b. Configuring ERPS ring member ports
   c. Configuring control VLANs
   d. Configuring protected VLANs
   e. Configuring the node role
3. Enabling ERPS for an instance
   Perform this task on all nodes on an ERPS ring.
4. (Optional.) Enabling R-APS packets to carry the ring ID in the destination MAC address
   Perform this task on all nodes on an ERPS ring.
5. (Optional.) Configuring R-APS packet levels
6. (Optional.) Setting ERPS timers
   Perform this task on the owner node on an ERPS ring.
7. (Optional.) Setting the non-revertive mode
   Perform this task on the owner node on an ERPS ring.
8. (Optional.) Setting a switchover mode
   Perform this task on the nodes that you want to block their ports.
9. (Optional.) Associating a ring with a subring
   Perform this task on the interconnection node on an ERPS ring.
10. (Optional.) Enabling flush packet transparent transmission
    Perform this task on the interconnection node on an ERPS ring.
11. (Optional.) Associating an ERPS ring member port with a track entry
12. (Optional.) Removing the MS mode and FS mode settings for an ERPS ring

Prerequisites

Before you configure ERPS, complete the following tasks:

- Establish the Ethernet ring topology.
- Determine the ERPS rings, ERPS instances, control VLANs, protected VLANs, and node roles.

Enabling ERPS globally

Restrictions and guidelines

- Perform this task on devices you want to configure as ERPS nodes.
- For ERPS to take effect for an instance, enable it globally first.

Procedure

1. Enter system view.

system-view

2. Enable ERPS globally.

   erps enable

   By default, ERPS is disabled globally.

Configuring an ERPS ring

Creating an ERPS ring

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- A ring ID uniquely identifies an ERPS ring. All nodes on an ERPS ring must be configured with the same ring ID.

Procedure

1. Enter system view.

   system-view

2. Create an ERPS ring.

   erps ring *ring-id*

3. (Optional.) Configure the ring type.

   ring-type sub-ring

   By default, an ERPS ring is a major ring.

Configuring ERPS ring member ports

Restrictions and guidelines

- Perform this task on each node's ports intended for accessing ERPS rings.
- ERPS ring member ports automatically allow packets from the control VLAN to pass through.
- Do not enable Ethernet OAM remote loopback for ERPS ring member ports. This feature might cause a broadcast storm. For more information about Ethernet OAM, see "Configuring Ethernet OAM."
- For faster topology convergence, use the **link-delay** command on ERPS ring member ports to set the physical state change suppression interval to 0 seconds. For more information about the **link-delay** command, see *Interface Command Reference*.
- You must configure ERPS ring member ports as trunk ports.
- Do not assign an interface to both an aggregation group and an ERPS ring. If you do so, the interface does not take effect on the ERPS ring and cannot be displayed by using the **display erps detail** command.

Configuring ERPS ring member port attributes

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*

3. Configure the port as a trunk port.

   port link-type trunk

By default, a port is an access port.

For more information about this command, see *Layer 2—LAN Switching Command Reference*.

4. Assign the trunk port to protected VLANs.

   port trunk permit vlan { *vlan-id-list* | **all** }

   By default, a trunk port is assigned only to VLAN 1.

   For more information about this command, see *Layer 2—LAN Switching Command Reference*.

5. Disable the spanning tree feature.

   undo stp enable

   By default, the spanning tree feature is enabled.

   For more information about this command, see *Layer 2—LAN Switching Command Reference*.

Configuring an ERPS ring member port

1. Enter system view.

   system-view

2. Enter ERPS ring view.

   erps ring *ring-id*

3. Configure an ERPS ring member port.

   { **port0** | **port1** } **interface** *interface-type interface-number*

   By default, an ERPS ring does not have ERPS ring member ports.

Configuring control VLANs

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- The control VLAN must be a VLAN that has not been created on the device.
- Configure the same control VLAN for all nodes in an ERPS instance.
- Do not configure the default VLAN of an ERPS ring member port as the control VLAN.
- Do not enable QinQ or VLAN mapping on control VLANs. If you do, ERPS packets cannot be correctly forwarded and received.
- Make sure the ERPS instance has been configured. After the ERPS instance is enabled, the control VLAN cannot be changed.
- For a device not configured with ERPS to transparently transmit ERPS packets, make sure only the two ports accessing the ERPS ring permit packets from the control VLAN. If other ports on the device permit packets from the control VLAN, the packets from other VLANs might enter the control VLAN and strike the ERPS ring.

Procedure

1. Enter system view.

   system-view

2. Enter ERPS ring view.

   erps ring *ring-id*

3. Enable ERPS instance view.

   instance *instance-id*

4. Configure a control VLAN.

   control-vlan *vlan-id*

Configuring protected VLANs

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- Configure the same protected VLAN for all nodes of an ERPS instance. To implement load balancing, configure different protected VLANs for different ERPS instances.

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enable ERPS instance view.
   instance *instance-id*
4. Configure the protected VLANs.
   protected-vlan reference-instance *instance-id-list*

Configuring the node role

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- For the owner node to work correctly, you must configure only one owner node for an ERPS ring.
- You can only configure the interconnection node for subrings.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Configure the node role.
   node-role { { **owner** | **neighbor** } **rpl** | **interconnection** } { **port0** | **port1** }
   By default, a node is a normal node.

Enabling ERPS for an instance

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.

- You can enable ERPS for an instance only when it is configured with a control VLAN and a protected VLAN.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Enable ERPS for the instance.
   instance enable
   By default, ERPS is disabled for an instance.

Enabling R-APS packets to carry the ring ID in the destination MAC address

About this task

Perform this task to configure the ring ID as the last byte of the destination MAC address for R-APS packets. The ring of R-APS packets can be identified by their destination MAC addresses.

Restrictions and guidelines

Perform this task on all nodes on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enable R-APS packets to carry the ring ID in the destination MAC address.
   r-aps ring-mac
   By default, R-APS packets do not carry ring IDs in their destination MAC addresses. The last byte of the destination MAC address is 1.

Configuring R-APS packet levels

Restrictions and guidelines

Perform this task on all nodes on an ERPS ring.

On a ring, the levels of R-APS packets must be the same for all nodes in an ERPS instance.

A node does not process R-APS packets whose levels are greater than the level of R-APS packets sent by the node.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.

erps ring *ring-id*

3. Enter ERPS instance view.
   instance *instance-id*
4. Configure the R-APS packet level.
   r-aps level *level-value*
   By default, the level for R-APS packets is 7.

Setting ERPS timers

Restrictions and guidelines

Perform this task on the owner node on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Set the guard timer.
   timer guard *guard-value*
   By default, the guard timer is 500 milliseconds.
5. Set the hold-off timer.
   timer hold-off *hold-off-value*
   By default, the hold-off timer is 0 milliseconds.
6. Set the WTR timer.
   timer wtr *wtr-value*
   By default, the WTR timer is 5 minutes.

Setting the non-revertive mode

About this task

Perform this task if you do not want to switch back to the recovered link after the link fault is cleared.

Restrictions and guidelines

Perform this task on the owner node on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Set the non-revertive mode.

revertive-operation non-revertive

By default, revertive mode is used.

Setting a switchover mode

Restrictions and guidelines

Perform this task on the nodes that you want to block their ports.

Procedure

1. Enter system view.

   system-view

2. Set a switchover mode.

   erps switch { **force** | **manual** } **ring** *ring-id* **instance** *instance-id* { **port0** | **port1** }

   By default, no switchover mode is not set.

Associating a ring with a subring

About this task

On a multi-ring network, perform this task if you want to advertise topology changes in a subring to a ring.

Restrictions and guidelines

Perform this task on the interconnection node on an ERPS ring.

Procedure

1. Enter system view.

   system-view

2. Enter ERPS ring view.

   erps ring *ring-id*

3. Configure the ERPS ring as a subring.

   ring-type sub-ring

   By default, an ERPS ring is a major ring.

4. Enter ERPS instance view.

   instance *instance-id*

5. Associate a ring with the subring.

   sub-ring connect ring *ring-id* **instance** *instance-id*

   By default, a subring is not associated with any rings.

Enabling flush packet transparent transmission

About this task

This feature enables the interconnection nodes to forward flush packets for topology changes in the subring to the ring associated with the subring. The associated ring can flush the MAC address table quickly to speed up convergence.

Restrictions and guidelines

Perform this task on the interconnection node on an ERPS ring.

To use this feature, you must also associate a subring on the interconnection node with the ring.

Procedure

1. Enter system view.
   system-view
2. Enable flush packet transparent transmission.
   erps tcn-propagation
   By default, flush packet transparent transmission is disabled.

Associating an ERPS ring member port with a track entry

Restrictions and guidelines

Before you associate a port with a track entry, make sure the port has joined an ERPS instance.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Associate an ERPS ring member port with a track entry.
   port erps ring *ring-id* **instance** *instance-id* **track** *track-entry-index*
   By default, an ERPS ring member port is not associated with any track entries.

Removing the MS mode and FS mode settings for an ERPS ring

About this task

After you configure this task, the owner node can ignore the WTR timer and immediately switch traffic to the recovered link upon link recovery.

This task also switches an ERPS ring in non-revertive mode to revertive mode.

Procedure

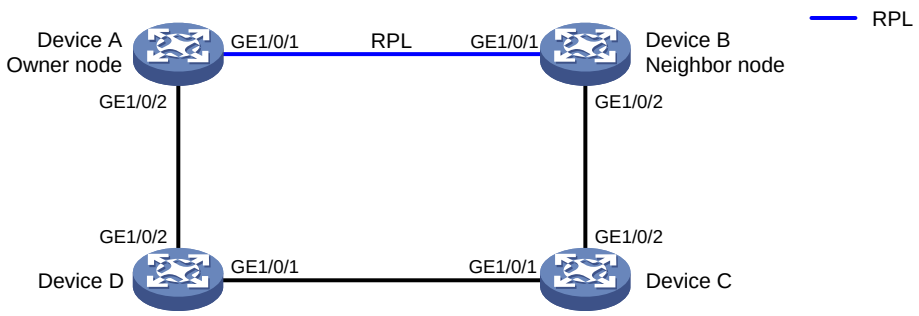
1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   erps clear ring *ring-id* **instance** *instance-id*

Displaying and maintaining ERPS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display brief ERPS information.	**display erps**
Display detailed ERPS information.	**display erps detail ring** *ring-id* [**instance** *instance-id*]
Display ERPS packet statistics.	**display erps statistics** [**ring** *ring-id* [**instance** *instance-id*]]
Clear ERPS packet statistics.	**reset erps statistics ring** *ring-id* [**instance** *instance-id*]

ERPS configuration examples



Example: Configuring one ring

Network configuration

As shown in Figure 11, perform the following tasks to eliminate loops on the network:

- Configure the ring as ERPS ring 1.
- Configure VLAN 100 as the control VLAN for ERPS ring 1.
- Configure VLANs 1 to 30 as the protected VLANs for ERPS ring 1.
- Configure Device A as the owner node, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Device B as the neighbor node, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Device C and Device D as normal nodes, GigabitEthernet 1/0/1 as ERPS ring member port 0, and GigabitEthernet 1/0/2 as ERPS ring member port 1.

Figure 11 Network diagram

Procedure

1. Configure Device A.

   # Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 1 to 30
   [DeviceA] stp region-configuration
   [DeviceA-mst-region] instance 1 vlan 1 to 30
   [DeviceA-mst-region] active region-configuration
   ```

```
[DeviceA-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceA] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceA-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceA-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Enable R-APS packets to carry ring ID in the destination MAC address.

```
[DeviceA-erps-ring1] r-aps ring-mac
```

Create ERPS instance 1.

```
[DeviceA-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceA-erps-ring1-inst1] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceA-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceA-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceA-erps-ring1-inst1] instance enable
[DeviceA-erps-ring1-inst1] quit
[DeviceA-erps-ring1] quit
```

Enable ERPS.

```
[DeviceA] erps enable
```

2. Configure Device B.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
```

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceB] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceB-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceB-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Enable R-APS packets to carry ring ID in the destination MAC address.

```
[DeviceB-erps-ring1] r-aps ring-mac
```

Create ERPS instance 1.

```
[DeviceB-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceB-erps-ring1-inst1] node-role neighbor rpl port0
```

Configure the control VLAN.

```
[DeviceB-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceB-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceB-erps-ring1-inst1] instance enable
[DeviceB-erps-ring1-inst1] quit
[DeviceB-erps-ring1] quit
```

Enable ERPS.

```
[DeviceB] erps enable
```

3. Configure Device C.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
[DeviceC] stp region-configuration
```

```
[DeviceC-mst-region] instance 1 vlan 1 to 30
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceC] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceC-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceC-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Enable R-APS packets to carry ring ID in the destination MAC address.

```
[DeviceC-erps-ring1] r-aps ring-mac
```

Create ERPS instance 1.

```
[DeviceC-erps-ring1] instance 1
```

Configure the control VLAN.

```
[DeviceC-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceC-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceC-erps-ring1-inst1] instance enable
[DeviceC-erps-ring1-inst1] quit
[DeviceC-erps-ring1] quit
```

Enable ERPS.

```
[DeviceC] erps enable
```

4. Configure Device D.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable

[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceD] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceD-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceD-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Enable R-APS packets to carry ring ID in the destination MAC address.

```
[DeviceD-erps-ring1] r-aps ring-mac
```

Create ERPS instance 1.

```
[DeviceD-erps-ring1] instance 1
```

Configure the control VLAN.

```
[DeviceD-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceD-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceD-erps-ring1-inst1] instance enable
[DeviceD-erps-ring1-inst1] quit
[DeviceD-erps-ring1] quit
```

Enable ERPS.

```
[DeviceD] erps enable
```

Verifying the configuration

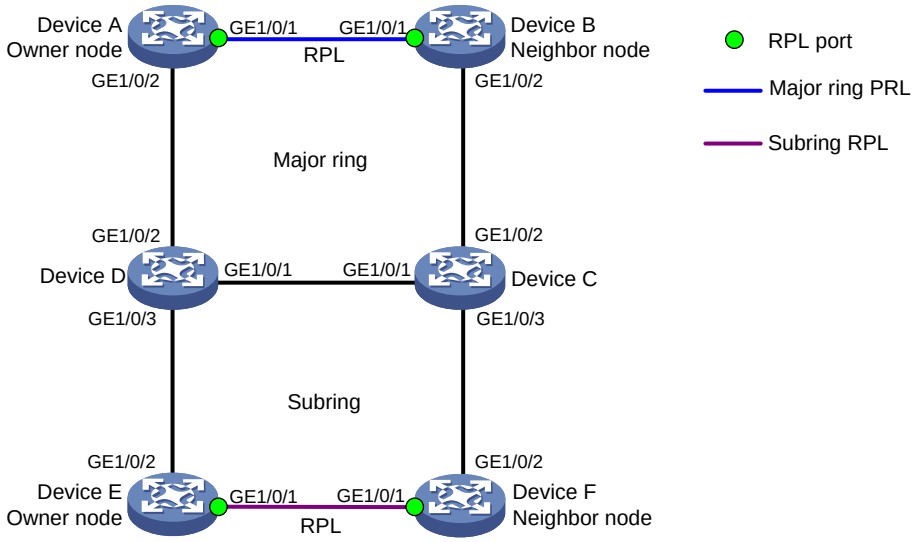
Display information about ERPS instance 1 for Device A.

```
[DeviceA] display erps detail ring 1
 Ring ID              : 1
 Port0                : GigabitEthernet1/0/1
 Port1                : GigabitEthernet1/0/2
 Subring              : No
 Default MAC          : No
```

```
Instance ID           : 1
Node role             : Owner
Node state            : Idle
Connect(ring/instance): -
Control VLAN          : 100
Protected VLAN        : Reference-instance 1
Guard timer           : 500 ms
Hold-off timer        : 0 ms
WTR timer             : 5 min
Revertive operation   : Revertive
Enable status         : Yes, Active status : Yes
R-APS level           : 7
Port                  PortRole               PortStatus
--------------------------------------------------------------------------------
Port0                 RPL                    Block
Port1                 Non-RPL                Up
```

The output shows the following information:

- Device A is the owner node.
- The ERPS ring is in idle state.
- The RPL port is blocked.
- The non-RPL port is unblocked.



Example: Configuring one subring

Network configuration

As shown in Figure 12, perform the following tasks to eliminate loops on the network:

- Configure VLAN 100 and VLAN 200 as the control VLANs for the major ring and the subring, respectively.
- Configure VLANs 1 to 30 as the protected VLANs for the major ring and subring.
- Configure Device A as the owner node for the major ring, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Device B as the neighbor node for the major ring, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Devices C and D as interconnection nodes, GigabitEthernet 1/0/1 as ERPS ring member port 0, GigabitEthernet 1/0/2 as ERPS ring member port 1, and GigabitEthernet 1/0/3 as the interconnection port.
- Configure Device E as the owner node for the subring, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Device F as the neighbor node for the subring, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.

Figure 12 Network diagram

Procedure

1. Configure Device A.

   # Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 1 to 30
   [DeviceA] stp region-configuration
   [DeviceA-mst-region] instance 1 vlan 1 to 30
   [DeviceA-mst-region] active region-configuration
   [DeviceA-mst-region] quit
   ```

   # Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] link-delay up 0
   [DeviceA-GigabitEthernet1/0/1] link-delay down 0
   ```

   # Disable the spanning tree feature on the port.

   ```
   [DeviceA-GigabitEthernet1/0/1] undo stp enable
   ```

   # Configure the port as a trunk port and assign it to VLANs 1 to 30.

   ```
   [DeviceA-GigabitEthernet1/0/1] port link-type trunk
   [DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] link-delay up 0
   [DeviceA-GigabitEthernet1/0/2] link-delay down 0
   [DeviceA-GigabitEthernet1/0/2] undo stp enable
   [DeviceA-GigabitEthernet1/0/2] port link-type trunk
   [DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

   # Create ERPS ring 1.

   ```
   [DeviceA] erps ring 1
   ```

   # Configure ERPS ring member ports.

```
[DeviceA-erps-ring1] port0 interface gigabitethernet 1/0/1

```

Create ERPS instance 1.

```
[DeviceA-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceA-erps-ring1-inst1] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceA-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceA-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceA-erps-ring1-inst1] instance enable
[DeviceA-erps-ring1-inst1] quit
[DeviceA-erps-ring1] quit
```

Enable ERPS.

```
[DeviceA] erps enable
```

2. Configure Device B.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```

```

Enable ERPS for instance 1.

```
[DeviceD-erps-ring2-inst1] instance enable
[DeviceD-erps-ring2-inst1] quit
[DeviceD-erps-ring2] quit
```

Enable ERPS.

```
[DeviceD] erps enable
```

5. Configure Device E.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceE> system-view
[DeviceE] vlan 1 to 30
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 1 vlan 1 to 30
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] link-delay up 0
[DeviceE-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] link-delay up 0
[DeviceE-GigabitEthernet1/0/2] link-delay down 0
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/2] quit
```

Create ERPS ring 2.

```
[DeviceE] erps ring 2
```

Configure ERPS ring member ports.

```
[DeviceE-erps-ring2] port0 interface gigabitethernet 1/0/1
[DeviceE-erps-ring2] port1 interface gigabitethernet 1/0/2
```

Configure ERPS ring 2 as the subring.

```
[DeviceE-erps-ring2] ring-type sub-ring
```

Create ERPS instance 1.

```
[DeviceE-erps-ring2] instance 1
```

Configure the node role.

```
[DeviceE-erps-ring2] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceE-erps-ring2-inst1] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceE-erps-ring2-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceE-erps-ring2-inst1] instance enable
[DeviceE-erps-ring2-inst1] quit
[DeviceE-erps-ring2] quit
```

Enable ERPS.

```
[DeviceE] erps enable
```

6. Configure Device F.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceF> system-view
[DeviceF] vlan 1 to 30
[DeviceF] stp region-configuration
[DeviceF-mst-region] instance 1 vlan 1 to 30
[DeviceF-mst-region] active region-configuration
[DeviceF-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceF] interface gigabitethernet 1/0/1
[DeviceF-GigabitEthernet1/0/1] link-delay up 0
[DeviceF-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceF-GigabitEthernet1/0/1] undo stp enable
[DeviceF-GigabitEthernet1/0/1] port link-type trunk
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceF-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceF-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceF] interface gigabitethernet 1/0/2
[DeviceF-GigabitEthernet1/0/2] link-delay up 0
[DeviceF-GigabitEthernet1/0/2] link-delay down 0
[DeviceF-GigabitEthernet1/0/2] undo stp enable
[DeviceF-GigabitEthernet1/0/2] port link-type trunk
[DeviceF-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceF-GigabitEthernet1/0/2] quit
```

Create ERPS ring 2.

```
[DeviceF] erps ring 2
```

Configure ERPS ring member ports.

```
[DeviceF-erps-ring2] port0 interface gigabitethernet 1/0/1
[DeviceF-erps-ring2] port1 interface gigabitethernet 1/0/2
```

Configure ERPS ring 2 as the subring.

```
[DeviceF-erps-ring2] ring-type sub-ring
```

Create ERPS instance 1.

```
[DeviceF-erps-ring2] instance 1
```

Configure the node role.

```
[DeviceF-erps-ring2] node-role neighbor rpl port0
```

Configure the control VLAN.

```
[DeviceF-erps-ring2-inst1] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceF-erps-ring2-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceF-erps-ring2-inst1] instance enable
[DeviceF-erps-ring2-inst1] quit
[DeviceF-erps-ring2] quit
```

Enable ERPS.

```
[DeviceF] erps enable
```

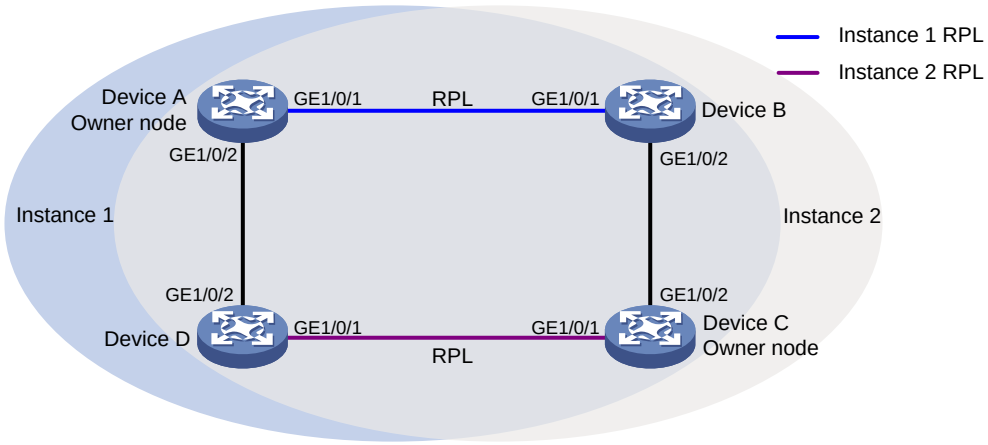
Verifying the configuration

Display information about ERPS instance 1 for Device A.

```
[Device A] display erps detail ring 1
 Ring ID               : 1
 Port0                 : GigabitEthernet1/0/1
 Port1                 : GigabitEthernet1/0/2
 Subring               : Yes
 Default MAC           : No
 Instance ID           : 1
 Node role             : Owner
 Node state            : Idle
 Connect(ring/instance): -
 Control VLAN          : 100
 Protected VLAN        : Reference-instance 1
 Guard timer           : 500 ms
 Hold-off timer        : 0 ms
 WTR timer             : 5 min
 Revertive operation   : Revertive
 Enable status         : Yes, Active status : Yes
 R-APS level           : 7
 Port                  PortRole                PortStatus
 --------------------------------------------------------------------------------
 Port0                 RPL                     Block
 Port1                 Non-RPL                 Up
```

The output shows the following information:

- Device A is the owner node.
- The ERPS ring is in idle state.
- The RPL port is blocked.
- The non-RPL port is unblocked.



Example: Configuring one-ring multi-instance load balancing

Network configuration

As shown in Figure 13, perform the following tasks to improve network resource utilization and implement load balancing among links:

- Configure ERPS instances 1 and 2 on the ERPS ring.
- For ERPS instance 1, configure the following items:
  - Configure Device A as the owner node.
  - Configure the link between Devices A and Device B as the RPL.
  - Configure VLAN 100 as the control VLAN.
  - Configure VLANs 1 to 30 as the protected VLANs.
- For ERPS instance 2, configure the following items:
  - Configure Device A as the owner node.
  - Configure the link between Devices C and Device D as the RPL.
  - Configure VLAN 100 as the control VLAN.
  - Configure VLANs 31 to 60 as the protected VLANs.

Figure 13 Network diagram

Procedure

1. Configure Device A.

Create VLANs 1 to 60, map VLANs 1 to 30 to MSTI 1, map VLANs 31 to 60 to MSTI 2, and activate the MST region configuration.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 60
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
[DeviceA-mst-region] instance 2 vlan 31 to 60
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 60.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 60
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 60
[DeviceA-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceA] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceA-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceA-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Create ERPS instance 1.

```
[DeviceA-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceA-erps-ring1-inst1] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceA-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceA-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceA-erps-ring1-inst1] instance enable
[DeviceA-erps-ring1-inst1] quit
[DeviceA-erps-ring1] quit
```

Create ERPS instance 2.

```
[DeviceA-erps-ring1] instance 2
```

Configure the control VLAN.

```
[DeviceA-erps-ring1-inst2] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceA-erps-ring1-inst2] protected-vlan reference-instance 2
```

Enable ERPS for instance 2.

```
[DeviceA-erps-ring1-inst2] instance enable
[DeviceA-erps-ring1-inst2] quit
[DeviceA-erps-ring1] quit
```

Enable ERPS.

```
[DeviceA] erps enable
```

2. Configure Device B.

Create VLANs 1 to 60, map VLANs 1 to 30 to MSTI 1, map VLANs 31 to 60 to MSTI 2, and activate the MST region configuration.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 60
```

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
[DeviceB-mst-region] instance 2 vlan 31 to 60
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 60.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 60
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 60
[DeviceB-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceB] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceB-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceB-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Create ERPS instance 1.

```
[DeviceB-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceB-erps-ring1-inst1] node-role neighbor rpl port0
```

Configure the control VLAN.

```
[DeviceB-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceB-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceB-erps-ring1-inst1] instance enable
[DeviceB-erps-ring1-inst1] quit
[DeviceB-erps-ring1] quit
```

Create ERPS instance 2.

```
[DeviceB-erps-ring1] instance 2
```

Configure the control VLAN.

```
[DeviceB-erps-ring1-inst2] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceB-erps-ring1-inst2] protected-vlan reference-instance 2
```

Enable ERPS for instance 2.

```
[DeviceB-erps-ring1-inst2] instance enable
[DeviceB-erps-ring1-inst2] quit
[DeviceB-erps-ring1] quit
```

Enable ERPS.

```
[DeviceB] erps enable
```

3. Configure Device C.

Create VLANs 1 to 60, map VLANs 1 to 30 to MSTI 1, map VLANs 31 to 60 to MSTI 2, and activate the MST region configuration.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 60
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
[DeviceC-mst-region] instance 2 vlan 31 to 60
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 60.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 60
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 60
[DeviceC-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceC] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceC-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceC-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Create ERPS instance 1.

```
[DeviceC-erps-ring1] instance 1
```

Configure the control VLAN.

```
[DeviceC-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceC-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceC-erps-ring1-inst1] instance enable
[DeviceC-erps-ring1-inst1] quit
```

```
[DeviceC-erps-ring1] quit
```

Create ERPS instance 2.

```
[DeviceC-erps-ring1] instance 2
```

Configure the node role.

```
[DeviceC-erps-ring1-inst2] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceC-erps-ring1-inst2] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceC-erps-ring1-inst2] protected-vlan reference-instance 2
```

Enable ERPS for instance 2.

```
[DeviceC-erps-ring1-inst2] instance enable
[DeviceC-erps-ring1-inst2] quit
[DeviceC-erps-ring1] quit
```

Enable ERPS.

```
[DeviceC] erps enable
```

4. Configure Device D.

Create VLANs 1 to 60, map VLANs 1 to 30 to MSTI 1, map VLANs 31 to 60 to MSTI 2, and activate the MST region configuration.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 60
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
[DeviceD-mst-region] instance 2 vlan 31 to 60
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 60.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 60
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 60
[DeviceD-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceD] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceD-erps-ring1] port0 interface gigabitethernet 1/0/1
```

```
[DeviceD-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Create ERPS instance 1.

```
[DeviceD-erps-ring1] instance 1
```

Configure the control VLAN.

```
[DeviceD-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceD-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceD-erps-ring1-inst1] instance enable
[DeviceD-erps-ring1-inst1] quit
```

Create ERPS instance 2.

```
[DeviceD-erps-ring1] instance 2
```

Configure the node role.

```
[DeviceD-erps-ring1-inst2] node-role neighbor rpl port0
```

Configure the control VLAN.

```
[DeviceD-erps-ring1-inst2] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceD-erps-ring1-inst2] protected-vlan reference-instance 2
```

Enable ERPS for instance 2.

```
[DeviceD-erps-ring1-inst2] instance enable
[DeviceD-erps-ring1-inst2] quit
[DeviceD-erps-ring1] quit
```

Enable ERPS.

```
[DeviceD] erps enable
```

Verifying the configuration

Display information about ERPS instance 1 for Device A.

```
[Device A] display erps detail ring 1
 Ring ID               : 1
 Port0                 : GigabitEthernet1/0/1
 Port1                 : GigabitEthernet1/0/2
 Subring               : No

 Port                  PortRole               PortStatus
 --------------------------------------------------------------------------------
 Port0                 RPL                    Block
```

```
Port1                   Non-RPL                 Up

 Instance ID            : 2
Node role               : Normal
Node state              : Idle
Connect(ring/instance): -
Control VLAN            : 100
Protected VLAN          : Reference-instance 2
Guard timer             : 500 ms
Hold-off timer          : 0 ms
WTR timer               : 5 min
Revertive operation     : Revertive
Enable status           : Yes, Active status : Yes
R-APS level             : 7
Port                    PortRole                PortStatus
--------------------------------------------------------------------------------
Port0                   Non-RPL                 Up
Port1                   Non-RPL                 Up
```

The output shows the following information:

- For ERPS instance 1:
  - Device A is the owner node.
  - The ERPS ring is in idle state.
  - The RPL port is blocked.
  - The non-RPL port is unblocked.
- For ERPS instance 2:
  - Device A is a normal node.
  - The ERPS ring is in idle state.
  - The non-RPL port is unblocked.

Troubleshooting ERPS

The owner node cannot receive SF packets from a faulty node when the link state is normal

Symptom

The link between the owner node and the faulty node is available, but the owner node cannot receive SF packets sent by the faulty node. The RPL port is blocked.

Analysis

Possible reasons include:

- ERPS is not enabled for some nodes on the ERPS ring.
- The ring IDs are different for the nodes on the same ERPS ring.
- The control VLAN IDs are different for the nodes in the same ERPS instance.
- A port on the ERPS ring is faulty.

Solutions

To resolve the problem:

- Use the **display erps** command to examine whether ERPS is enabled for all nodes on the ERPS ring. If ERPS is disabled for some nodes, use the **erps enable** command to enable ERPS for the nodes.
- Set the same ring ID for all nodes on a ERPS ring and configure the same control VLAN for all nodes in an ERPS instance.
- Use the **display erps detail** command to examine the port status for all nodes. Bring up the ports in down state.
- Use the **debugging erps** command on all nodes to view debugging information about packets and node status.

Configuring Smart Link

About Smart Link

Application scenario

Smart Link is an H3C-proprietary protocol that provides link redundancy and subsecond convergence time in a dual uplink network. As shown in Figure 1, Smart Link is configured on Device C and Device D. The secondary link takes over quickly when the primary link fails.

Figure 1 Dual uplink network diagram

A Smart Link network has the following devices:

- **Smart Link devices**—A Smart Link device has two uplinks. A Smart Link device must be configured with a smart link group and a transmit control VLAN to transmit flush messages. Device C and Device D in Figure 1 are Smart Link devices.
- **Associated devices**—An associated device is an uplink device to which Smart Link devices are connected. An associated device supports Smart Link, and receives flush messages sent from the specified control VLAN. When a primary/secondary link switchover occurs, the associated device updates the MAC address entries and ARP/ND entries according to received flush messages. Device A, Device B, and Device E in Figure 1 are associated devices.

Terminology

Smart link group

A smart link group consists of only two member ports: the primary and the secondary ports. Only one port is active for forwarding at a time, and the other port is blocked and in standby state. When link failure occurs on the active port due to port shutdown or the presence of unidirectional link, the standby port becomes active and takes over. The original active port transits to the blocked state.

As shown in Figure 1, Port C1 and Port C2 of Device C form a smart link group. Port C1 is active, and Port C2 is standby. Port D1 and Port D2 of Device D form another smart link group. Port D1 is active, and Port D2 is standby.

Primary/secondary port

Primary port and secondary port are two port types in a smart link group. When both ports in a smart link group are up, the primary port preferentially transits to the forwarding state. The secondary port stays in standby state. When the primary port fails, the secondary port takes over to forward traffic.

As shown in Figure 1, Port C1 of Device C and Port D1 of Device D are primary ports. Port C2 of Device C and Port D2 of Device D are secondary ports.

Primary/secondary link

The link that connects the primary port in a smart link group is the primary link. The link that connects the secondary port is the secondary link.

Flush message

When link switchover occurs, the smart link group uses flush messages to notify other devices to refresh their MAC address entries and ARP/ND entries. Flush messages are common multicast data packets, and will be dropped by a blocked receiving port.

Protected VLAN

A smart link group controls the forwarding state of protected VLANs. Each smart link group on a port controls a different protected VLAN. The state of the port in a protected VLAN is determined by the state of the port in the smart link group.

Transmit control VLAN

The transmit control VLAN is used for transmitting flush messages. When link switchover occurs, the devices (such as Device C and Device D in Figure 1) send flush messages within the transmit control VLAN.

Receive control VLAN

The receive control VLAN is used for receiving and processing flush messages. When link switchover occurs, the devices (such as Device A, Device B, and Device E in Figure 1) receive and process flush messages in the receive control VLAN. In addition, they refresh their MAC address entries and ARP/ND entries.

How Smart Link works

Link backup

As shown in Figure 1, the link on Port C1 of Device C is the primary link. The link on Port C2 of Device C is the secondary link. Port C1 is in forwarding state, and Port C2 is in standby state. When the primary link fails, Port C2 takes over to forward traffic and Port C1 is blocked and placed in standby state.

When a port switches to the forwarding state, the system outputs log information to notify the user of the port state change.

Topology change

Link switchover might outdate the MAC address entries and ARP/ND entries on all devices. A flush update mechanism is provided to ensure correct packet transmission. With this mechanism, a Smart Link-enabled device updates its information by transmitting flush messages over the backup link to its upstream devices. This mechanism requires the upstream devices to be capable of recognizing Smart Link flush messages to update their MAC address forwarding entries and ARP/ND entries.

Preemption mode

As shown in Figure 1, the link on Port C1 of Device C is the primary link. The link on Port C2 of Device C is the secondary link. When the primary link fails, Port C1 is automatically blocked and placed in standby state, and Port C2 takes over to forward traffic. When the primary link recovers, one of the following actions occurs:

- If the smart link group is not configured with a preemption mode, Port C1 stays blocked to keep traffic forwarding stable. Port C1 does not take over to forward traffic until the next link switchover.
- If the smart link group is configured with a preemption mode and the preemption conditions are met, Port C1 takes over to forward traffic as soon as its link recovers. Port C2 is automatically blocked and placed in standby state.

Load sharing

A ring network might carry traffic of multiple VLANs. Smart Link can forward traffic from different VLANs in different smart link groups for load sharing.

To implement load sharing, you can assign a port to multiple smart link groups. Configure each group with a different protected VLAN. Make sure the state of the port is different in these smart link groups, so traffic from different VLANs can be forwarded along different paths.

You can configure protected VLANs for a smart link group by referencing Multiple Spanning Tree Instances (MSTIs). For more information about MSTIs, see *Layer 2—LAN Switching Configuration Guide*.

Collaboration between Smart Link and Monitor Link for port status detection

Smart Link cannot detect when faults occur on the uplink of the upstream devices or when faults are cleared. You can configure the Monitor Link function to monitor the status of the uplink ports of the upstream devices. Monitor Link adapts the up/down state of downlink ports to uplink ports, and triggers Smart Link to perform link switchover on the downstream device. For more information about Monitor Link, see "Configuring Monitor Link."

Collaboration between Smart Link and Track for link status detection

Smart Link cannot detect unidirectional links, misconnected fibers, or packet loss on intermediate devices or network paths of the uplink. It cannot detect when faults are cleared either. To detect link status, smart link group member ports must use link detection protocols. When a fault is detected or cleared, the link detection protocols inform Smart Link to switch over the links.

Smart Link collaborates with link detection protocols through track entries. It supports only the Continuity Check (CC) function of Connectivity Fault Detection (CFD) to implement link detection. CFD notifies the smart link group member ports of fault detection events by using detection VLANs and detection ports. A port responds to a continuity check event only when the control VLAN of the smart link group to which it belongs matches the detection VLAN. For more information about track entries and the CC function of CFD, see "Configuring Track" and "Configuring CFD."

Restrictions and guidelines: Smart Link configuration

When you configure Smart Link, follow these restrictions and guidelines:

- If you configure a port as both an aggregation group member and a smart link group member, only the aggregation group configuration takes effect. The port is not shown in the output from the **display smart-link group** command. The smart link group configuration takes effect after the port leaves the aggregation group.

Smart Link tasks at a glance

To configure Smart Link, perform the following tasks:

1. Configuring a Smart Link device
   a. Configuring protected VLANs for a smart link group
   b. Configuring member ports for a smart link group
   c. (Optional.) Configuring a preemption mode for a smart link group
   d. (Optional.) Enabling the sending of flush messages
   e. (Optional.) Configuring collaboration between Smart Link and Track
2. Enabling an associated device to receive flush messages

Configuring a Smart Link device

Prerequisites for Smart Link device configuration

Before configuring a Smart Link device, complete the following tasks:

- To prevent loops, shut down a port before configuring it as a smart link group member. You can bring up the port only after completing the smart link group configuration.
- Disable the spanning tree feature, RRPP, and ERPS on the ports you want to add to the smart link group.

Configuring protected VLANs for a smart link group

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configration Guide*.

Procedure

1. Enter system view.
   system-view
2. Create a smart link group and enter smart link group view.
   smart-link group *group-id*
3. Configure protected VLANs for the smart link group.
   protected-vlan reference-instance *instance-id-list*

Configuring member ports for a smart link group

Restrictions and guidelines

You can configure member ports for a smart link group either in smart link group view or in interface view. The configurations made in these two views have the same effect.

In smart link group view

1. Enter system view.
   system-view
2. Create a smart link group and enter smart link group view.
   smart-link group *group-id*
3. Configure member ports for a smart link group.
   port *interface-type interface-number* { **primary** | **secondary** }
   By default, no member port is configured for a smart link group.

In interface view

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure member ports for a smart link group.
   port smart-link group *group-id* { **primary** | **secondary** }
   By default, an interface is not a smart link group member.

Configuring a preemption mode for a smart link group

1. Enter system view.
   system-view
2. Enter smart link group view.
   smart-link group *group-id*
3. Configure a preemption mode for the smart link group.
   preemption mode { **role** | **speed** [**threshold** *threshold-value*] }
   By default, preemption is disabled.
4. Configure the preemption delay.
   preemption delay *delay*
   By default, the preemption delay is 1 second.
   The preemption delay configuration takes effect only after a preemption mode is configured.

Enabling the sending of flush messages

Restrictions and guidelines

- The control VLAN configured for a smart link group must be different from the control VLAN configured for any other smart link group.
- Make sure the configured control VLAN already exists, and assign the smart link group member ports to the control VLAN.

- The control VLAN of a smart link group must also be one of its protected VLANs. Do not remove the control VLAN. Otherwise, flush messages cannot be sent correctly.

Procedure

1. Enter system view.
   system-view
2. Enter smart link group view.
   smart-link group *group-id*
3. Enable flush update.
   flush enable [**control-vlan** *vlan-id*]
   By default, flush update is enabled, and VLAN 1 is the control VLAN.

Configuring collaboration between Smart Link and Track

About this task

Smart Link collaborates with the CC function of CFD through track entries to implement link detection.

Prerequisites

Before you configure collaboration between Smart Link and Track on a port, you must assign the port to the smart link group.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure collaboration between Smart Link and Track on the port.
   port smart-link group *group-id* **track** *track-entry-number*
   By default, smart link group member ports do not collaborate with track entries.

Enabling an associated device to receive flush messages

Restrictions and guidelines

- You do not need to enable all ports on the associated devices to receive flush messages. Enable the feature only on all control VLANs of ports on the primary and secondary links between the Smart Link device and the destination device.
- If no control VLAN is specified for processing flush messages, the device forwards the received flush messages without any processing.
- Make sure the receive control VLAN is the same as the transmit control VLAN configured on the Smart Link device. If they are not the same, the associated device will forward the received flush messages directly without any processing.
- Do not remove the control VLANs. Otherwise, flush messages cannot be sent correctly.
- Make sure the control VLANs are existing VLANs, and assign the ports capable of receiving flush messages to the control VLANs.

Prerequisites

Disable the spanning tree feature on the associated device's ports that connect to the member ports of the smart link group. Otherwise, the ports will discard flush messages when they are not in forwarding state if a topology change occurs.

Procedure

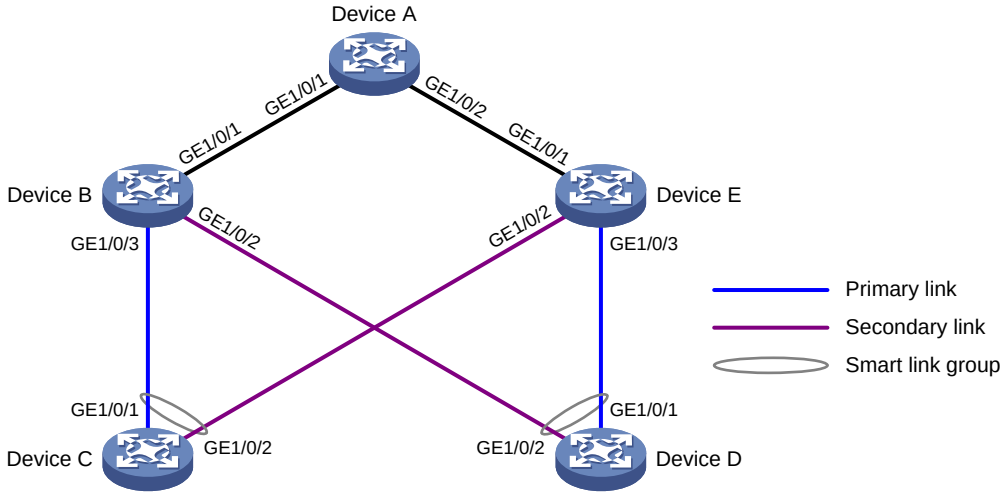
1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure the control VLANs for receiving flush messages.
   smart-link flush enable [**control-vlan** *vlan-id-list*]
   By default, no control VLAN receives flush messages.

Display and maintenance commands for Smart Link

Execute **display** commands in any view and the **reset** command in user view:

Task	Command
Display information about the received flush messages.	**display smart-link flush**
Display smart link group information.	**display smart-link group** { *group-id* | **all** }
Clear the statistics about flush messages.	**reset smart-link statistics**

Smart Link configuration examples



Example: Configuring a single smart link group

Network configuration

As shown in Figure 2:

- Device C and Device D are Smart Link devices. Device A, Device B, and Device E are associated devices. Traffic of VLANs 1 through 30 on Device C and Device D is dually uplinked to Device A.
- Configure Smart Link on Device C and Device D for dual uplink backup.

Figure 2 Network diagram

Procedure

1. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs.

```
[DeviceC] smart-link group 1
```

```
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable flush message sending in smart link group 1, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] flush enable control-vlan 10
[DeviceC-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 again.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] shutdown
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs.

```
[DeviceD] smart-link group 1
[DeviceD-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceD-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceD-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable flush message sending in smart link group 1, and configure VLAN 20 as the transmit control VLAN.

```
[DeviceD-smlk-group1] flush enable control-vlan 20
[DeviceD-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 again.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] undo shutdown
[DeviceD-GigabitEthernet1/0/1] quit
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] undo shutdown
[DeviceD-GigabitEthernet1/0/2] quit
```

3. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 20 as the receive control VLAN on the port.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 20
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/3] undo stp enable
```

Enable flush message receiving and configure VLAN 10 as the receive control VLAN on the port.

```
[DeviceB-GigabitEthernet1/0/3] smart-link flush enable control-vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

4. Configure Device E:

Create VLANs 1 through 30.

```
<DeviceE> system-view
[DeviceE] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceE-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 as the receive control VLAN on the port.

```
[DeviceE-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10
[DeviceE-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/3
[DeviceE-GigabitEthernet1/0/3] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/3] undo stp enable
```

Enable flush message receiving and configure VLAN 20 as the receive control VLAN on the port.

```
[DeviceE-GigabitEthernet1/0/3] smart-link flush enable control-vlan 20
[DeviceE-GigabitEthernet1/0/3] quit
```

5. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 20
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

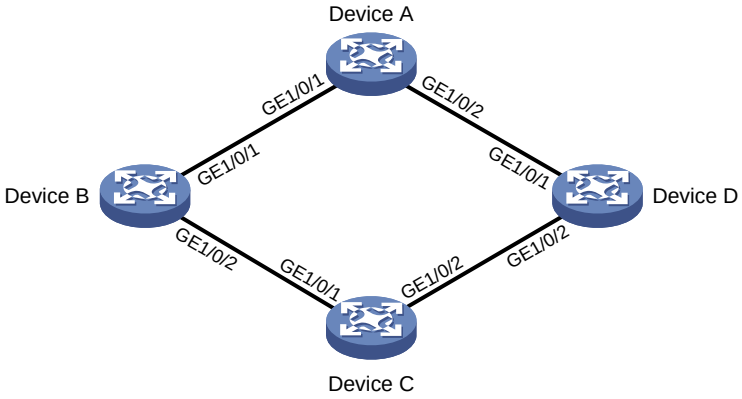
Display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group 1
Smart link group 1 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : None
  Preemption delay: 1(s)
  Control VLAN    : 10
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   ACTIVE  5               16:45:20 2012/04/21
  GE1/0/2                 SECONDARY STANDBY 1               16:37:20 2012/04/21
```

Display the flush messages received on Device B.

```
[DeviceB] display smart-link flush
 Received flush packets                              : 5
 Receiving interface of the last flush packet        : GigabitEthernet1/0/3
 Receiving time of the last flush packet             : 16:50:21 2012/04/21
 Device ID of the last flush packet                  : 000f-e23d-5af0
 Control VLAN of the last flush packet               : 10
```



Example: Configuring multiple smart link groups load sharing

Network configuration

As shown in Figure 3:

- Device C is a Smart Link device. Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 200 on Device C is dually uplinked to Device A by Device B and Device D.
- Implement dual uplink backup and load sharing on Device C. Traffic of VLANs 1 through 100 is uplinked to Device A by Device B. Traffic of VLANs 101 through 200 is uplinked to Device A by Device D.

Figure 3 Network diagram

Procedure

1. Configure Device C:

Create VLAN 1 through VLAN 200.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 200
```

Map VLANs 1 through 100 to MSTI 1, and VLANs 101 through 200 to MSTI 2.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 100
[DeviceC-mst-region] instance 2 vlan 101 to 200
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLAN 1 through VLAN 200.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable role preemption in smart link group 1, enable flush message sending, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] preemption mode role
[DeviceC-smlk-group1] flush enable control-vlan 10
[DeviceC-smlk-group1] quit
```

Create smart link group 2, and configure all VLANs mapped to MSTI 2 as the protected VLANs for smart link group 2.

```
[DeviceC] smart-link group 2
[DeviceC-smlk-group2] protected-vlan reference-instance 2
```

Configure GigabitEthernet 1/0/1 as the secondary port and GigabitEthernet 1/0/2 as the primary port for smart link group 2.

```
[DeviceC-smlk-group2] port gigabitethernet 1/0/2 primary
[DeviceC-smlk-group2] port gigabitethernet 1/0/1 secondary
```

Enable role preemption in smart link group 2, enable flush message sending, and configure VLAN 110 as the transmit control VLAN.

```
[DeviceC-smlk-group2] preemption mode role
[DeviceC-smlk-group2] flush enable control-vlan 110
[DeviceC-smlk-group2] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device B:

Create VLAN 1 through VLAN 200.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device D:

Create VLAN 1 through VLAN 200.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/2] quit
```

4. Configure Device A:

Create VLAN 1 through VLAN 200.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
```

```
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group all
Smart link group 1 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : Role
  Preemption delay: 1(s)
  Control VLAN    : 10
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   ACTIVE  5               16:45:20 2012/04/21

Smart link group 2 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : Role
  Preemption delay: 1(s)
  Control VLAN    : 110
  Protected VLAN  : Reference Instance 2

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/2                 PRIMARY   ACTIVE  5               16:45:20 2012/04/21
  GE1/0/1                 SECONDARY STANDBY 1               16:37:20 2012/04/21
```

Display the flush messages received on Device B.

```
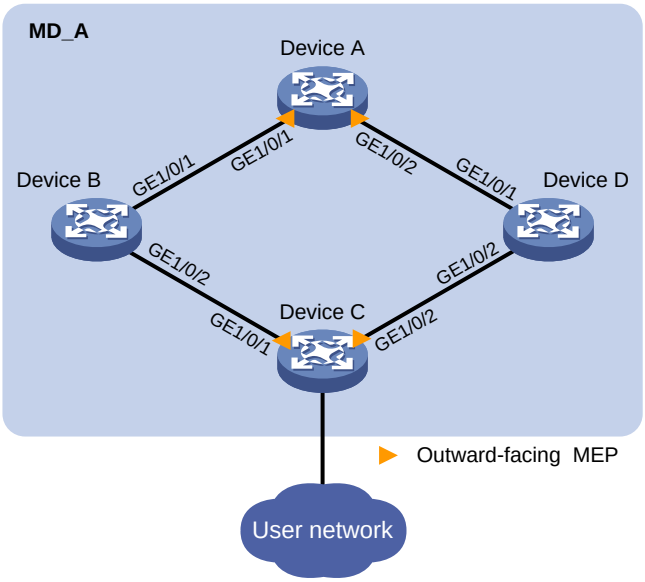
[DeviceB] display smart-link flush
 Received flush packets                          : 5
 Receiving interface of the last flush packet    : GigabitEthernet1/0/2
 Receiving time of the last flush packet         : 16:25:21 2012/04/21
 Device ID of the last flush packet              : 000f-e23d-5af0
 Control VLAN of the last flush packet           : 10
```

Example: Configuring Smart Link and Track collaboration

Network configuration



As shown in Figure 4:

- Device A, Device B, Device C, and Device D form maintenance domain (MD) **MD_A** of level 5. Device C is a Smart Link device, and Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 200 on Device C is dually uplinked to Device A by Device B and Device D.
- Configure collaboration between Smart Link and the CC function of CFD through track entries to meet the following requirements:
  - Traffic of VLANs 1 through 100 is uplinked to Device A by Device C through GigabitEthernet 1/0/1 (primary port of smart link group 1).

- Traffic of VLANs 101 through 200 is uplinked to Device A by Device C through GigabitEthernet 1/0/2 (primary port of smart link group 2).
- When the link between Device C and Device A fails, traffic is quickly switched to the secondary port of each smart link group. After the fault is cleared, traffic is switched back to the primary ports.

For more information about CFD, see "Configuring CFD."

Figure 4 Network diagram

Procedure

1. Configure Device A:

   # Create VLAN 1 through VLAN 200.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 1 to 200
   ```

   # Configure GigabitEthernet 1/0/1 as a trunk port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] port link-type trunk
   ```

   # Assign the port to VLANs 1 through 200.

   ```
   [DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
   ```

   # Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

   ```
   [DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] port link-type trunk
   [DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
   [DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

   # Enable CFD and create MD **MD_A** of level 5.

   ```
   [DeviceA] cfd enable
   [DeviceA] cfd md MD_A level 5
   ```

Create service instance 1 in which the MA name is based on the VLAN ID in **MD_A** and configure the MA to serve VLAN 10.

```
[DeviceA] cfd service-instance 1 ma-id vlan-based md MD_A vlan 10
```

Create a MEP list in service instance 1, create outward-facing MEP 1002, and enable CCM sending in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] cfd meplist 1001 1002 service-instance 1
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] cfd mep 1002 service-instance 1 outbound
[DeviceA-GigabitEthernet1/0/1] cfd cc service-instance 1 mep 1002 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

Create service instance 2 in which the MA name is based on the VLAN ID in **MD_A** and configure the MA to serve VLAN 110.

```
[DeviceA] cfd service-instance 2 ma-id vlan-based md MD_A vlan 110
```

Create a MEP list in service instance 2, create outward-facing MEP 1002, and enable CCM sending in service instance 2 on GigabitEthernet 1/0/2.

```
[DeviceA] cfd meplist 2001 2002 service-instance 2
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] cfd mep 2002 service-instance 2 outbound
[DeviceA-GigabitEthernet1/0/2] cfd cc service-instance 2 mep 2002 enable
[DeviceA-GigabitEthernet1/0/2] quit
```

2. Configure Device B:

Create VLAN 1 through VLAN 200.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device C:

Create VLAN 1 through VLAN 200.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 200
```

Map VLANs 1 through 100 to MSTI 1 and VLANs 101 through 200 to MSTI 2.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 100
[DeviceC-mst-region] instance 2 vlan 101 to 200
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable role preemption in smart link group 1, enable flush message sending, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] preemption mode role
[DeviceC-smlk-group1] flush enable control-vlan 10
[DeviceC-smlk-group1] quit
```

Create smart link group 2, and configure all VLANs mapped to MSTI 2 as the protected VLANs for smart link group 2.

```
[DeviceC] smart-link group 2
[DeviceC-smlk-group2] protected-vlan reference-instance 2
```

Configure GigabitEthernet 1/0/1 as the secondary port and GigabitEthernet 1/0/2 as the primary port for smart link group 2.

```
[DeviceC-smlk-group2] port gigabitethernet 1/0/2 primary
[DeviceC-smlk-group2] port gigabitethernet 1/0/1 secondary
```

Enable role preemption in smart link group 2, enable flush message sending, and configure VLAN 110 as the transmit control VLAN.

```
[DeviceC-smlk-group2] preemption mode role
```

```
[DeviceC-smlk-group2] flush enable control-vlan 110
[DeviceC-smlk-group2] quit
```

Enable CFD and create MD **MD_A** of level 5.

```
[DeviceC] cfd enable
[DeviceC] cfd md MD_A level 5
```

Create service instance 1 in which the MA name is based on the VLAN ID in **MD_A** and configure the MA to serve VLAN 10.

```
[DeviceC] cfd service-instance 1 ma-id vlan-based md MD_A vlan 10
```

Create a MEP list in service instance 1. Create outward-facing MEP 1001, and enable CCM sending in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceC] cfd meplist 1001 1002 service-instance 1
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] cfd mep 1001 service-instance 1 outbound
[DeviceC-GigabitEthernet1/0/1] cfd cc service-instance 1 mep 1001 enable
[DeviceC-GigabitEthernet1/0/1] quit
```

Create service instance 2 in which the MA name is based on the VLAN ID in **MD_A** and configure the MA to serve VLAN 110.

```
[DeviceC] cfd service-instance 2 ma-id vlan-based md MD_A vlan 110
```

Create a MEP list in service instance 2. Create outward-facing MEP 2001. Enable CCM sending in service instance 2 on GigabitEthernet 1/0/2.

```
[DeviceC] cfd meplist 2001 2002 service-instance 2
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] cfd mep 2001 service-instance 2 outbound
[DeviceC-GigabitEthernet1/0/2] cfd cc service-instance 2 mep 2001 enable
[DeviceC-GigabitEthernet1/0/2] quit
```

Create track entry 1 that is associated with the CFD CC function of MEP 1001 in service instance 1.

```
[DeviceC] track 1 cfd cc service-instance 1 mep 1001
```

Configure collaboration between the primary port GigabitEthernet 1/0/1 of smart link group 1 and the CC function of CFD through track entry 1, and bring up the port.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port smart-link group 1 track 1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
```

Create track entry 1 that is associated with the CFD CC function of MEP 1001 in service instance 1.

```
[DeviceC] track 2 cfd cc service-instance 2 mep 2001
```

Configure collaboration between the primary port GigabitEthernet 1/0/2 of smart link group 2 and the CC function of CFD through track entry 2, and bring up the port.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] port smart-link group 2 track 2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

4. Configure Device D:

Create VLAN 1 through VLAN 200.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/2] quit
```

Verifying the configuration

When the optical fiber between Device A and Device B fails, display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group all
Smart link group 1 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : Role
  Preemption delay: 1(s)
  Control VLAN    : 10
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   DOWN    5               16:45:20 2012/04/21
  GE1/0/2                 SECONDARY ACTIVE  1               16:37:20 2012/04/21

Smart link group 2 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : Role
  Preemption delay: 1(s)
  Control VLAN    : 110
  Protected VLAN  : Reference Instance 2

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/2                 PRIMARY   ACTIVE  5               16:45:20 2012/04/21
  GE1/0/1                 SECONDARY STANDBY 1               16:37:20 2012/04/21
```

The output shows that primary port GigabitEthernet 1/0/1 of smart link group 1 fails, and secondary port GigabitEthernet 1/0/2 is in forwarding state.

Configuring Monitor Link

About Monitor Link

Monitor Link is an H3C-proprietary protocol that associates the state of downlink interfaces with the state of uplink interfaces in a monitor link group. When Monitor Link shuts down the downlink interfaces because of an uplink failure, the downstream device changes connectivity to another link.

Figure 1 Monitor Link application scenario

A monitor link group contains uplink and downlink interfaces. An interface can belong to only one monitor link group.

- Uplink interfaces are the monitored interfaces.
- Downlink interfaces are the monitoring interfaces.

As shown in Figure 1:

- Port B1 and Port B2 of Device B form a monitor link group. Port B1 is an uplink interface, and Port B2 is a downlink interface.
- Port D1 and Port D2 of Device D form another monitor link group. Port D1 is an uplink interface, and Port D2 is a downlink interface.

A monitor link group works independently of other monitor link groups. When a monitor link group does not contain any uplink interface or all its uplink interfaces are down, the monitor link group goes down. It forces all downlink interfaces down at the same time. When any uplink interface comes up, the monitor link group comes up and brings up all the downlink interfaces.

Restrictions and guidelines: Monitor Link configuration

Follow these restrictions and guidelines when you configure Monitor Link:

- Do not manually shut down or bring up the downlink interfaces in a monitor link group.
- To avoid frequent state changes of downlink interfaces in the event that uplink interfaces in the monitor link group flap, you can configure a switchover delay. The switchover delay is the time that the downlink interfaces wait before they come up following an uplink interface.

Monitor Link tasks at a glance

To configure Monitor Link, perform the following tasks:

- Enabling Monitor Link globally
- Creating a monitor link group
- Configuring monitor link group member interfaces
- (Optional.) Configuring the uplink interface threshold for triggering monitor link group state switchover
- (Optional.) Configuring the switchover delay for the downlink interfaces in a monitor link group

Enabling Monitor Link globally

About this task

All monitor link groups can operate only after you enable Monitor Link globally. When you disable Monitor Link globally, all monitor link groups cannot operate and the downlink interfaces brought down by the monitor link groups resume their original states.

Procedure

1. Enter system view.
   `system-view`
2. Enable Monitor Link globally.
   `undo monitor-link disable`
   By default, Monitor Link is enabled globally.

Creating a monitor link group

1. Enter system view.
   `system-view`
2. Create a monitor link group and enter monitor link group view.
   `monitor-link group` *`group-id`*

Configuring monitor link group member interfaces

Restrictions and guidelines

- An interface can be assigned to only one monitor link group.
- To avoid undesired down/up state changes on the downlink interfaces, configure uplink interfaces before you configure downlink interfaces.
- If you have configured a Selected port of an aggregation group as the downlink interface of a monitor link group, do not configure an Unselected port of the aggregation group as the uplink interface of the monitor link group.
- Do not add an aggregate interface and its member ports to the same monitor link group.
- You can configure member interfaces for a monitor link group in monitor link group view or interface view. Configurations made in these views have the same effect. The configuration is supported by the following interfaces:
  - Layer 2 Ethernet interfaces.
  - Layer 2 aggregate interfaces.
  - Loopback interfaces.
  - VLAN interfaces.

Configuring monitor link group member interfaces in monitor link group view

1. Enter system view.
   system-view
2. Enter monitor link group view.
   monitor-link group *group-id*
3. Configure member interfaces for the monitor link group.
   port *interface-type interface-number* { **downlink** | **uplink** }
   By default, no member interfaces exist in a monitor link group.

Configuring monitor link group member interfaces in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the interface as a member of a monitor link group.
   port monitor-link group *group-id* { **downlink** | **uplink** }
   By default, the interface is not a monitor link group member.

Configuring the uplink interface threshold for triggering monitor link group state switchover

1. Enter system view.
   system-view
2. Enter monitor link group view.
   monitor-link group *group-id*
3. Configure the uplink interface threshold for triggering monitor link group state switchover.
   uplink up-port-threshold *number-of-port*
   By default, the uplink interface threshold for triggering monitor link group state switchover is 1.

Configuring the switchover delay for the downlink interfaces in a monitor link group

1. Enter system view.
   system-view
2. Enter monitor link group view.
   monitor-link group *group-id*
3. Configure the switchover delay for the downlink interfaces in the monitor link group.
   downlink up-delay *delay*
   By default, the switchover delay is 0 seconds. The downlink interfaces come up as soon as an uplink interface comes up.

Display and maintenance commands for Monitor Link

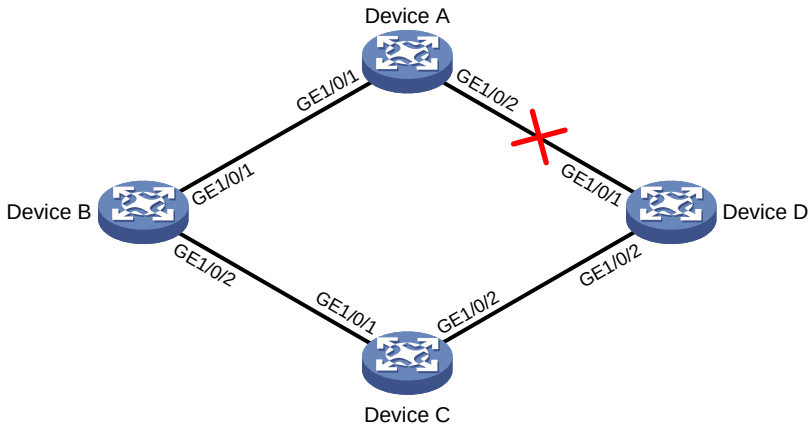
Execute the **display** command in any view:

Task	Command
Display monitor link group information.	**display monitor-link group** { *group-id* | **all** }

Monitor Link configuration examples

Example: Configuring Monitor Link

Network configuration



As shown in Figure 2:

- Device C is a Smart Link device, and Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 30 on Device C is dual-uplinked to Device A through a smart link group.

- Implement dual uplink backup on Device C. When the link between Device A and Device B (or Device D) fails, Device C can detect the link fault. It then performs uplink switchover in the smart link group.

For more information about Smart Link, see "Configuring Smart Link."

Figure 2 Network diagram

Procedure

1. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the interface.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the interface as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all the VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable the smart link group to transmit flush messages.

```
[DeviceC-smlk-group1] flush enable
[DeviceC-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable
[DeviceA-GigabitEthernet1/0/2] quit
```

3. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable
```

```
[DeviceB-GigabitEthernet1/0/1] quit
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Configure the interface as a trunk port.

```
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Create monitor link group 1.

```
[DeviceB] monitor-link group 1
```

Configure GigabitEthernet 1/0/1 as an uplink interface for monitor link group 1.

```
[DeviceB-mtlk-group1] port gigabitethernet 1/0/1 uplink
```

Configure GigabitEthernet 1/0/2 as a downlink interface for monitor link group 1.

```
[DeviceB-mtlk-group1] port gigabitethernet 1/0/2 downlink
[DeviceB-mtlk-group1] quit
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable
[DeviceD-GigabitEthernet1/0/1] quit
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] undo stp enable
```

Configure the interface as a trunk port.

```
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable
[DeviceD-GigabitEthernet1/0/2] quit
```

Create monitor link group 1.

```
[DeviceD] monitor-link group 1
```

Configure GigabitEthernet 1/0/1 as an uplink interface for monitor link group 1.

```
[DeviceD-mtlk-group1] port gigabitethernet 1/0/1 uplink
```

Configure GigabitEthernet 1/0/2 as a downlink interface for monitor link group 1.

```
[DeviceD-mtlk-group1] port gigabitethernet 1/0/2 downlink
```

```
[DeviceD-mtlk-group1] quit
```

Verifying the configuration

When GigabitEthernet 1/0/2 on Device A goes down because of a link fault, verify information about monitor link group 1 on Device B.

```
[DeviceB] display monitor-link group 1
Monitor link group 1 information:
  Group status     : UP
  Downlink up-delay: 0(s)
  Last-up-time     : 16:38:26 2012/4/21
  Last-down-time   : 16:37:20 2012/4/21
  Up-port-threshold: 1

  Member                    Role       Status
  ----------------------------------------------
  GE1/0/1                   UPLINK     UP
  GE1/0/2                   DOWNLINK   UP
```

Verify information about monitor link group 1 on Device D.

```
[DeviceD] display monitor-link group 1
Monitor link group 1 information:
  Group status     : DOWN
  Downlink up-delay: 0(s)
  Last-up-time     : 16:37:20 2012/4/21
  Last-down-time   : 16:38:26 2012/4/21
  Up-port-threshold: 1

  Member                    Role       Status
  ----------------------------------------------
  GE1/0/1                   UPLINK     DOWN
  GE1/0/2                   DOWNLINK   DOWN (Monitor Link)
```

Configuring VRRP

About VRRP

Typically, you can configure a default gateway for every host on a LAN. All packets destined for other networks are sent through the default gateway. As shown in Figure 1, when the default gateway fails, no hosts can communicate with external networks.

Figure 1 LAN networking

Using a default gateway facilitates your configuration but requires high availability. Using more egress gateways improves link availability but introduces the problem of routing among the egresses.

Virtual Router Redundancy Protocol (VRRP) is designed to address this issue. VRRP adds a group of network gateways to a VRRP group called a virtual router. The VRRP group has one master and multiple backups, and provides a virtual IP address. The hosts on the subnet use the virtual IP address as their default network gateway to communicate with external networks.

VRRP avoids single points of failure and simplifies the configuration on hosts. When the master in the VRRP group on a multicast or broadcast LAN (for example, an Ethernet network) fails, another router in the VRRP group takes over. The switchover is complete without causing dynamic route recalculation, route re-discovery, gateway reconfiguration on the hosts, or traffic interruption.

VRRP operates in either of the following modes:

- **Standard mode**—Implemented based on RFCs. For more information, see "VRRP standard mode."
- **Load balancing mode**—Extends the VRRP standard mode to distribute load across VRRP group members. For more information, see "VRRP load balancing mode."

VRRP has two versions: VRRPv2 and VRRPv3. VRRPv2 supports IPv4 VRRP. VRRPv3 supports IPv4 VRRP and IPv6 VRRP.

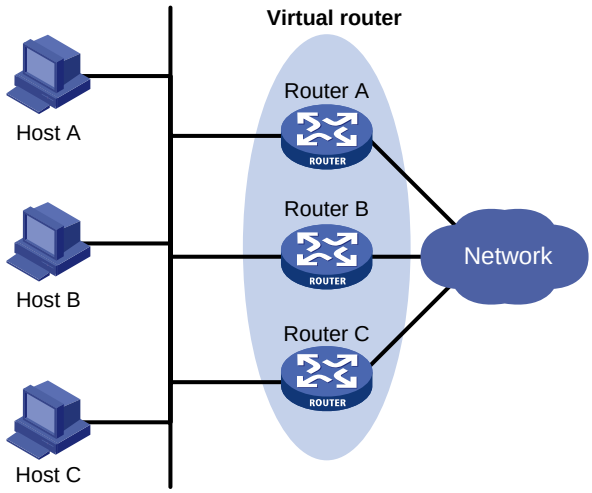
VRRP group

VRRP adds a group of network gateways to a VRRP group called a virtual router. The VRRP group has one master and multiple backups, and provides a virtual IP address. The hosts on the subnet use the virtual IP address as their default network gateway to communicate with external networks.

The administrator can add a router to a VRRP group by creating the VRRP group on a Layer 3 interface on the router.

NOTE:

On a device, the interfaces added to VRRP groups having the same VRRP group number belong to different VRRP groups.



VRRP standard mode

VRRP networking

As shown in Figure 2, Router A, Router B, and Router C form a virtual router, which has a manually configured virtual IP address. Hosts on the subnet use the virtual router as the default gateway.

The router with the highest priority among the three routers is elected as the master, and the other two are backups. Only the master in the VRRP group can provide gateway service. When the master fails, the backup routers elect a new master to take over for nonstop gateway service.

Figure 2 VRRP networking

Virtual IP address and IP address owner

The virtual IP address of the virtual router can be either of the following IP addresses:

- Unused IP address on the subnet where the VRRP group resides.
- IP address of an interface on a router in the VRRP group.

In the latter case, the router is called the IP address owner. A VRRP group can have only one IP address owner.

Router priority in a VRRP group

VRRP determines the role (master or backup) of each router in a VRRP group by priority. A router with higher priority is more likely to become the master.

A VRRP priority can be in the range of 0 to 255, and a greater number represents a higher priority. Priorities 1 to 254 are configurable. Priority 0 is reserved for special uses, and priority 255 is for the

IP address owner. The IP address owner in a VRRP group always has a running priority of 255 and acts as the master as long as it operates correctly.

Preemption

A router in a VRRP group operates in either non-preemptive mode or preemptive mode.

- **Non-preemptive mode**—The master router acts as the master as long as it operates correctly, even if a backup router is later assigned a higher priority. Non-preemptive mode helps avoid frequent switchover between the master and backup routers.
- **Preemptive mode**—A backup starts a new master election and takes over as master when it detects that it has a higher priority than the current master. Preemptive mode ensures that the router with the highest priority in a VRRP group always acts as the master.

Authentication method

To avoid attacks from unauthorized users, VRRP member routers add authentication keys in VRRP packets to authenticate one another. VRRP provides the following authentication methods:

- Simple authentication

  The sender fills an authentication key into the VRRP packet, and the receiver compares the received authentication key with its local authentication key. If the two authentication keys match, the received VRRP packet is legitimate. Otherwise, the received packet is illegitimate and gets discarded.
- MD5 authentication

  The sender computes a digest for the VRRP packet by using the authentication key and MD5 algorithm, and saves the result to the packet. The receiver performs the same operation with the authentication key and MD5 algorithm, and compares the result with the content in the authentication header. If the results match, the received VRRP packet is legitimate. Otherwise, the received packet is illegitimate and gets discarded.

On a secure network, you can choose to not authenticate VRRP packets.

NOTE:

IPv4 VRRPv3 and IPv6 VRRPv3 do not support VRRP packet authentication.

VRRP timers

Skew_Time

Skew_Time helps avoid the situation that multiple backups in a VRRP group become the master when the master in the VRRP group fails.

Skew_Time is not configurable; its value depends on the VRRP version.

- In VRRPv2 (described in RFC 3768), Skew_Time is (256 – Router priority)/256.
- In VRRPv3 (described in RFC 5798), Skew_Time is ((256 – Router priority) × VRRP advertisement interval)/256.

VRRP advertisement interval

The master in a VRRP group periodically sends VRRP advertisements to declare its presence.

You can configure the interval at which the master sends VRRP advertisements. If a backup does not receive any VRRP advertisement when the timer (3 × VRRP advertisement interval + Skew_Time) expires, it takes over as the master.

VRRP preemption delay timer

You can configure the VRRP preemption delay timer for the following purposes:

- Avoid frequent state changes among members in a VRRP group.
- Provide the backups with enough time to collect information (such as routing information).

In preempt mode, a backup does not immediately become the master after it receives an advertisement with lower priority than the local priority. Instead, it waits for a period of time (preemption delay time + Skew_Time) before taking over as the master.

Master election

Routers in a VRRP group determine their roles by priority. When a router joins a VRRP group, it has a backup role. The router role changes according to the following situations:

- If the backup does not receive any VRRP advertisement when the timer (3 × advertisement interval + Skew_Time) expires, it becomes the master.
- If the backup receives a VRRP advertisement with the same or greater priority within the timer (3 × advertisement interval + Skew_Time), it remains a backup.
- If the backup receives a VRRP advertisement with a smaller priority within the timer (3 × advertisement interval + Skew_Time), the following results apply:
  - It remains a backup when operating in non-preemptive mode.
  - It becomes the master when operating in preemptive mode.

The elected master starts a VRRP advertisement interval to periodically send VRRP advertisements to notify the backups that it is operating correctly. Each of the backups starts a timer to wait for advertisements from the master.

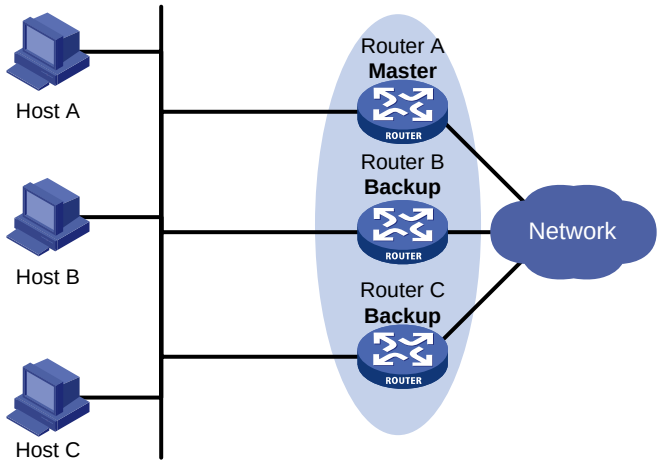
When multiple routers in a VRRP group declare that they are the master because of network problems, the one with the highest priority becomes the master. If two routers have the same priority, the one with the highest IP address becomes the master.

VRRP tracking

The VRRP tracking function uses network quality analyzer (NQA) or bidirectional forwarding detection (BFD) to monitor the state of the master or the upstream link. The collaboration between VRRP and NQA or BFD through a track entry implements the following functions:

- Monitors the upstream link and changes the priority of the router according to the state of the link. If the upstream link fails, the hosts on the subnet cannot access external networks through the router and the state of the track entry becomes Negative. The priority of the master decreases by a specified value, and a router with a higher priority in the VRRP group becomes the master. The switchover ensures uninterrupted communication between the hosts on the subnet and external networks.
- Monitors the state of the master on the backups. When the master fails, a backup immediately takes over to ensure uninterrupted communication.

When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority. For more information about track entries, see "Configuring Track."



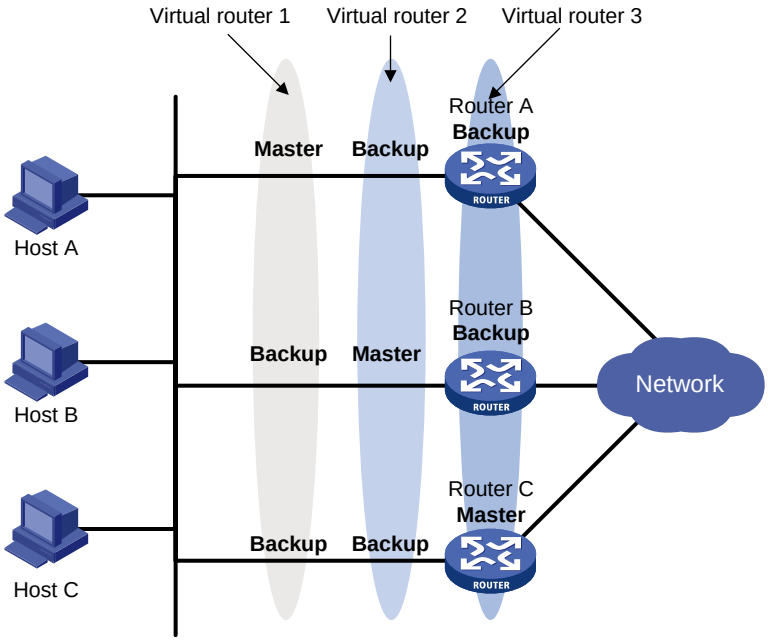
To enable VRRP tracking, configure the routers in the VRRP group to operate in preemptive mode first. This configuration ensures that only the router with the highest priority operates as the master.

VRRP application

Master/backup

In master/backup mode, only the master forwards packets, as shown in Figure 3. When the master fails, a new master is elected from among the backups. This mode requires only one VRRP group, and each router in the group has a different priority. The one with the highest priority becomes the master.

Figure 3 VRRP in master/backup mode



Assume that Router A is acting as the master to forward packets to external networks, and Router B and Router C are backups in listening state. When Router A fails, Router B and Router C elect a new master to forward packets for hosts on the subnet.

Load sharing

A router can join multiple VRRP groups. With different priorities in different VRRP groups, the router can act as the master in one VRRP group and a backup in another.

In load sharing mode, multiple VRRP groups provide gateway services. This mode requires a minimum of two VRRP groups, and each group has one master and multiple backups. The master roles in the VRRP groups are assumed by different routers, as shown in Figure 4.

Figure 4 Load sharing of VRRP

A router can be in multiple VRRP groups and have a different priority in each group.

As shown in Figure 4, the following VRRP groups exist:

- **VRRP group 1**—Router A is the master. Router B and Router C are the backups.
- **VRRP group 2**—Router B is the master. Router A and Router C are the backups.
- **VRRP group 3**—Router C is the master. Router A and Router B are the backups.

To implement load sharing among Router A, Router B, and Router C, perform the following tasks:

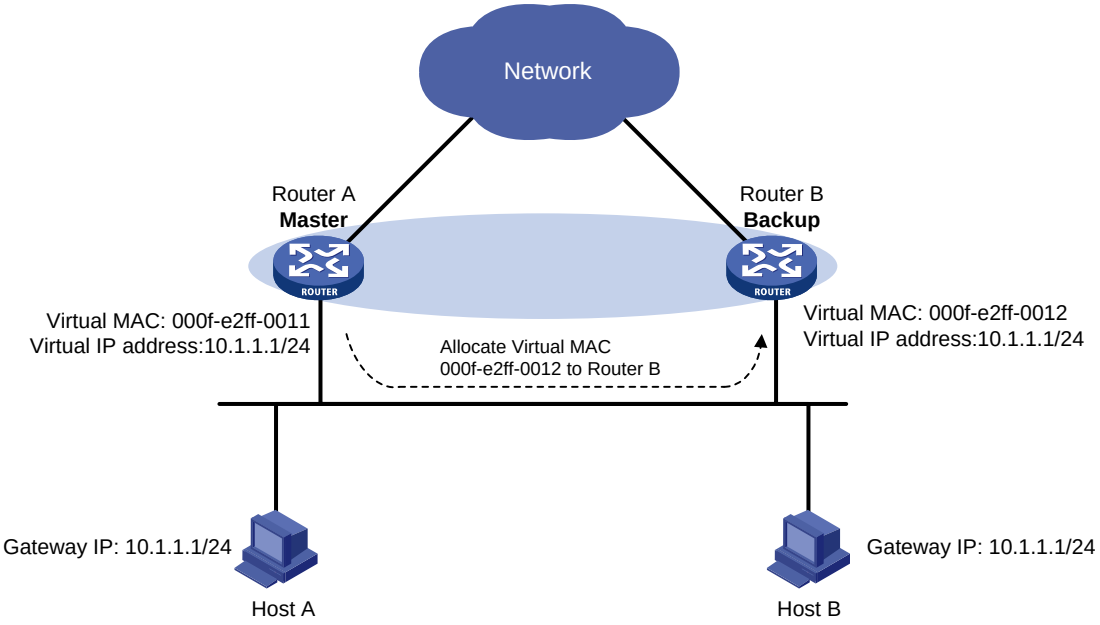
- Configure the virtual IP addresses of VRRP group 1, 2, and 3 as default gateway IP addresses for hosts on the subnet.
- Assign the highest priority to Router A, B, and C in VRRP group 1, 2, and 3, respectively.

VRRP load balancing mode

In a standard-mode VRRP group, only the master can forward packets and backups are in listening state. You can create multiple VRRP groups to share traffic, but you must configure different gateways for hosts on the subnet.

In load balancing mode, a VRRP group maps its virtual IP address to multiple virtual MAC addresses, assigning one virtual MAC address to each member router. Every router in this VRRP group can forward traffic and respond to IPv4 ARP requests or IPv6 ND requests from hosts. Because their virtual MAC addresses are different, traffic from hosts is distributed across the VRRP group members. Load balancing mode simplifies configuration and improves forwarding efficiency.

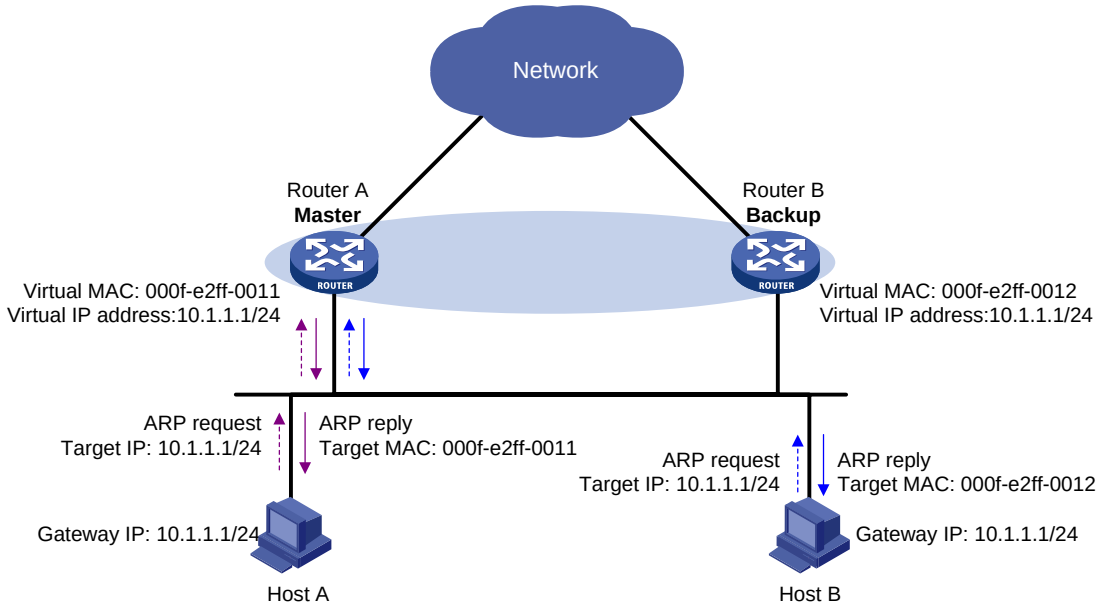
VRRP load balancing mode uses the same master election, preemption, and tracking mechanisms as the standard mode. New mechanisms have been introduced to VRRP load balancing mode, as described in the following sections.



Virtual MAC address assignment

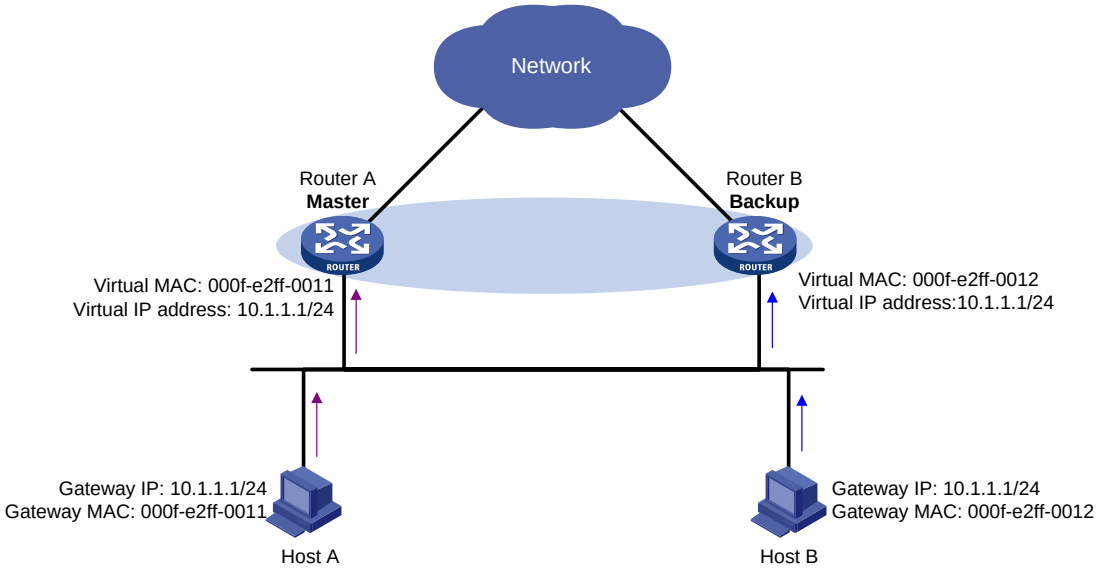
In load balancing mode, the master assigns virtual MAC addresses to routers in the VRRP group. The master uses different MAC addresses to respond to ARP requests or ND requests from different hosts. The backup routers, however, do not answer ARP requests or ND requests from hosts.

In an IPv4 network, a load balanced VRRP group works as follows:



1. The master assigns virtual MAC addresses to all member routers, including itself. This example assumes that the virtual IP address of the VRRP group is 10.1.1.1/24, Router A is the master, and Router B is the backup. Router A assigns 000f-e2ff-0011 for itself and 000f-e2ff-0012 for Router B. See Figure 5.

   Figure 5 Virtual MAC address assignment



2. When an ARP request arrives, the master (Router A) selects a virtual MAC address based on the load balancing algorithm to answer the ARP request. In this example, Router A returns the virtual MAC address of itself in response to the ARP request from Host A. Router A returns the virtual MAC address of Router B in response to the ARP request from Host B. See Figure 6.

   Figure 6 Answering ARP requests

3. Each host sends packets to the returned MAC address. As shown in Figure 7, Host A sends packets to Router A and Host B sends packets to Router B.

Figure 7 Sending packets to different routers for forwarding

In the ARP reply sent by the master, the source MAC address in the Ethernet header is different from the sender MAC address in the message body. For the Layer 2 device to forward the ARP packet, follow these configuration guidelines on the Layer 2 device:

- Do not enable ARP packet source MAC address consistency check.
- Do not specify the **src-mac** keyword when you enable ARP packet validity check for ARP detection.

For more information about ARP packet source MAC address consistency check and ARP detection, see *Security Configuration Guide*.

Virtual forwarder

Virtual forwarder creation

Virtual MAC addresses enable traffic distribution across routers in a VRRP group. To enable routers in the VRRP group to forward packets, VFs must be created on them. Each VF is associated with a virtual MAC address in the VRRP group and forwards packets that are sent to this virtual MAC address.

VFs are created on routers in a VRRP group, as follows:

1. The master assigns virtual MAC addresses to all routers in the VRRP group. Each member router creates a VF for this MAC address and becomes the owner of this VF.
2. Each VF owner advertises its VF information to the other member routers.
3. After receiving the VF advertisement, each of the other routers creates the advertised VF.

Eventually, every member router maintains one VF for each virtual MAC address in the VRRP group.

VF weight and priority

The weight of a VF indicates the forwarding capability of a VF. A higher weight means higher forwarding capability. When the weight is lower than the lower limit of failure, the VF cannot forward packets.

The priority of a VF determines the VF state. Among the VFs created on different member routers for the same virtual MAC address, the VF with the highest priority is in active state. This VF, known as the active virtual forwarder (AVF), forwards packets. All other VFs listen to the state of the AVF and are known as the listening virtual forwarders (LVFs). VF priority is in the range of 0 to 255, where 255

is reserved for the VF owner. When the weight of a VF owner is higher than or equal to the lower limit of failure, the priority of the VF owner is 255.

The priority of a VF is calculated based on its weight.

- If the VF weight is higher than or equal to the lower limit of failure, the following VF priorities apply:
  - On a VF owner, the VF priority is 255.
  - On a non-VF owner, the VF priority is calculated as weight/(number of local AVFs + 1).
- If the VF weight is lower than the lower limit of failure, the VF priority is 0.

VF backup

The VFs corresponding to a virtual MAC address on different routers in the VRRP group back up one another.

Figure 8 VF information

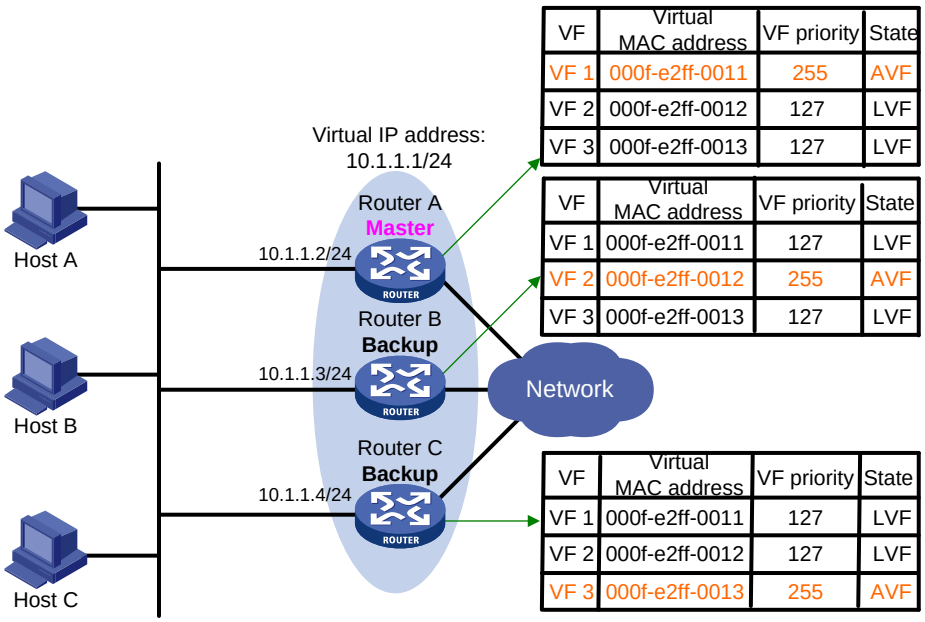


Figure 8 shows the VF table on each router in the VRRP group and how the VFs back up one another. The master, Router A, assigns virtual MAC addresses 000f-e2ff-0011, 000f-e2ff-0012, and 000f-e2ff-0013 to itself, Router B, and Router C, respectively. Each router creates VF 1, VF 2, and VF 3 for virtual MAC addresses 000f-e2ff-0011, 000f-e2ff-0012, and 000f-e2ff-0013, respectively. The VFs for the same virtual MAC address on different routers back up one another. For example, the VF 1 instances on Router A, Router B, and Router C back up one another.

- The VF 1 instance on Router A (the VF 1 owner) has priority 255. It acts as the AVF to forward packets sent to virtual MAC address 000f-e2ff-0011.
- The VF 1 instances on Router B and Router C have a priority of 255/(1 + 1), or 127. Because their priorities are lower than the priority of the VF 1 instance on Router A, they act as LVFs. These LVFs listen to the state of the VF 1 instance on Router A.
- When the VF 1 instance on Router A fails, the VF 1 instances on Router B and Router C elect the one with higher priority as the new AVF. This AVF forwards packets destined for virtual MAC address 000f-e2ff-0011. If the two LVFs' priorities are the same, the LVF with a greater device MAC address becomes the new AVF.

A VF always operates in preemptive mode. When an LVF finds its priority value higher than the one advertised by the AVF, the LVF declares itself as the AVF.

VF timers

When the AVF on a router fails, the new AVF on another router creates the following timers for the failed AVF:

- **Redirect timer**—Before this timer expires, the master still uses the virtual MAC address corresponding to the failed AVF to respond to ARP/ND requests from hosts. The VF owner can share traffic load if the VF owner resumes normal operation within this time. When this timer expires, the master stops using the virtual MAC address corresponding to the failed AVF to respond to ARP/ND requests from hosts.
- **Timeout timer**—The duration after which the new AVF takes over responsibilities of the failed VF owner. Before this timer expires, all routers in the VRRP group keep the VFs that correspond to the failed AVF. The new AVF forwards packets destined for the virtual MAC address of the failed AVF. When this timer expires, all routers in the VRRP group remove the VFs that correspond to the failed AVF, including the new AVF. Packets destined for the virtual MAC address of the failed AVF are not forwarded any longer.

VF tracking

An AVF forwards packets destined for the MAC address of the AVF. If the AVF's upstream link fails but no LVF takes over, the hosts that use the AVF's MAC address as their gateway MAC address cannot access the external network.

The VF tracking function can solve this problem. You can use NQA or BFD to monitor the upstream link state of the VF owner, and associate the VFs with NQA or BFD through the tracking function. This enables the collaboration between VRRP and NQA or BFD through the Track module. When the upstream link fails, the state of the track entry changes to Negative. The weights of the VFs (including the AVF) on the router decrease by a specific value. The corresponding LVF with a higher priority on another router becomes the AVF and forwards packets.

Protocols and standards

- RFC 3768, *Virtual Router Redundancy Protocol (VRRP)*
- RFC 5798, *Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6*

Configuring IPv4 VRRP

Restrictions and guidelines: IPv4 VRRP configuration

Configuration on the routers in an IPv4 VRRP group must be consistent.

Each IPv4 VRRP group corresponds to a virtual MAC address. The maximum number of IPv4 VRRP groups supported on an interface depends on the maximum number of virtual MAC addresses supported on the interface.

IPv4 VRRP tasks at a glance

To configure IPv4 VRRP, perform the following tasks:

1. Specifying an IPv4 VRRP operating mode
2. (Optional.) Specifying the IPv4 VRRP version
3. Configuring an IPv4 VRRP group
4. (Optional.) Configuring IPv4 VRRP packet attributes
5. (Optional.) Configuring VF tracking

   This configuration takes effect only in VRRP load balancing mode.

6. (Optional.) Setting the packet sending mode for IPv4 VRRPv3
7. (Optional.) Enabling periodic sending of gratuitous ARP packets for IPv4 VRRP
8. (Optional.) Configuring a subordinate IPv4 VRRP group to follow a master IPv4 VRRP group
9. (Optional.) Enabling SNMP notifications for VRRP

Specifying an IPv4 VRRP operating mode

Restrictions and guidelines

After an IPv4 VRRP operating mode is configured on a router, all IPv4 VRRP groups on the router operate in the specified operating mode.

When you change the VRRP group operating mode from standard to load balancing, follow these restrictions and guidelines:

- The VRRP virtual MAC address will also change.
- The original VRRP virtual MAC address in the ARP table of the neighbor device is not refreshed until the ARP entry ages out.

Before the VRRP virtual MAC address is refreshed, temporary service traffic interruption might occur. As a best practice, perform such operations during off-peak hours to minimize service impact.

Procedure

1. Enter system view.
   system-view
2. Specify an IPv4 VRRP operating mode.
   - Specify the standard mode.
     undo vrrp mode
   - Specify the load balancing mode.
     vrrp mode load-balance [**version-8**]

   By default, VRRP operates in standard mode.

Specifying the IPv4 VRRP version

About this task

IPv4 VRRP can use VRRPv2 and VRRPv3.

Restrictions and guidelines

For an IPv4 VRRP group to operate correctly, make sure the same VRRP version is used on all routers in the IPv4 VRRP group.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the version of VRRP.
   vrrp version *version-number*

   By default, VRRPv3 is used.

Configuring an IPv4 VRRP group

About this task

A VRRP group can operate correctly after you create it and assign a minimum of one virtual IP address to it. You can configure multiple virtual IP addresses for the VRRP group on an interface that connects to multiple subnets for router backup on different subnets.

If you disable an IPv4 VRRP group, the VRRP group enters **Initialize** state, and the existing configuration on the VRRP group remains unchanged. You can modify the configuration of the VRRP group. The modification takes effect when you enable the VRRP group again.

Restrictions and guidelines

Item	Remarks
VLAN interface	Do not create a VRRP group on the VLAN interface of a super VLAN because network performance might be adversely affected. For information about the super VLAN feature, see *Layer 2—LAN Switching Configuration Guide*.
Maximum number of VRRP groups and virtual IP addresses	In VRRP load balancing mode, the device supports a maximum of *MaxVRNum/N* VRRP groups. *MaxVRNum* refers to the maximum number of VRRP groups supported by the device in VRRP standard mode. *N* refers to the number of devices in the VRRP group.
Virtual IP address	When VRRP is operating in standard mode, the virtual IP address of a VRRP group can be either of the following addresses: • Unused IP address on the subnet where the VRRP group resides. • IP address of an interface on a router in the VRRP group. In load balancing mode, the virtual IP address of a VRRP group can be any unassigned IP address of the subnet where the VRRP group resides. It cannot be the IP address of any interfaces in the VRRP group. No IP address owner can exist in a VRRP group. An IPv4 VRRP group without virtual IP addresses configured can exist on a device provided that other settings (for example, priority and preemption mode) are available. Such a VRRP group stays in inactive state and does not function. For hosts in the subnet to access external networks, as a best practice, configure the following addresses in the same subnet: • Virtual IP address of an IPv4 VRRP group. • Downlink interface IP addresses of the VRRP group members.
IP address owner	On an IP address owner, as a best practice, do not use the **network** command to enable OSPF on the interface owning the virtual IP address of the VRRP group. For more information about the **network** command, see *Layer 3—IP Routing Command Reference*. After you remove the VRRP group on an IP address owner, a backup in the VRRP group takes over as the master. The actual IP address of the interface on the IP address owner will conflict with the virtual IP address of the new master. To avoid the conflict, change the IP address of the interface on the IP address owner before you remove the VRRP group from the interface. The running priority of an IP address owner is always 255, and you do not need to configure it. An IP address owner always operates in preemptive mode. If you configure the **vrrp vrid track priority reduced** or **vrrp vrid track switchover** command on an IP address owner, the configuration does not take effect until the router becomes a non-IP address owner.

Item	Remarks
VRRP association with a track entry	When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority or the failed master router becomes the master again.

Creating a VRRP group and assigning a virtual IP address

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Create a VRRP group and assign a virtual IP address.
   vrrp vrid *virtual-router-id* **virtual-ip** *virtual-address*

Configuring an IPv4 VRRP group

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the priority of the router in the VRRP group.
   vrrp vrid *virtual-router-id* **priority** *priority-value*

   The default setting is 100.
4. Enable the preemptive mode for the router in a VRRP group and set the preemption delay time.
   vrrp vrid *virtual-router-id* **preempt-mode** [**delay** *delay-value*]

   By default, the router in a VRRP group operates in preemptive mode and the preemption delay time is 0 centiseconds, which means an immediate preemption.
5. Associate a VRRP group with a track entry.
   vrrp vrid *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }

   By default, a VRRP group is not associated with any track entries.

Disabling an IPv4 VRRP group

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Disable a VRRP group.
   vrrp vrid *virtual-router-id* **shutdown**

   By default, an IPv4 VRRP group is enabled.

CAUTION:

You can use this command to temporarily disable an IPv4 VRRP group. After you execute this command, packets sent to the IPv4 VRRP group might be discarded.

Configuring IPv4 VRRP packet attributes

Restrictions and guidelines

- You can configure different authentication modes and authentication keys for VRRP groups on an interface. However, members of the same VRRP group must use the same authentication mode and authentication key.
- In VRRPv2, all routers in a VRRP group must have the same VRRP advertisement interval.
- In VRRPv3, authentication mode and authentication key settings do not take effect.
- In VRRPv3, routers in an IPv4 VRRP group can have different intervals for sending VRRP advertisements. The master in the VRRP group sends VRRP advertisements at specified intervals, and carries the interval in the advertisements. After a backup receives the advertisement, it records the interval in the advertisement. If the backup does not receive a VRRP advertisement before the timer (3 x recorded interval + Skew_Time) expires, it regards the master as failed and takes over.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the authentication mode and authentication key for an IPv4 VRRP group to send and receive VRRP packets.

   vrrp vrid *virtual-router-id* **authentication-mode** { **md5** | **simple** } { **cipher** | **plain** } *string*

   By default, authentication is disabled.

4. Set the interval at which the master in an IPv4 VRRP group sends VRRP advertisements.

   vrrp vrid *virtual-router-id* **timer advertise** *adver-interval*

   The default setting is 100 centiseconds.

   As a best practice to maintain system stability, set the VRRP advertisement interval to be greater than 100 centiseconds.

5. Specify the source interface for receiving and sending VRRP packets.

   vrrp vrid *virtual-router-id* **source-interface** *interface-type interface-number*

   By default, the source interface for receiving and sending VRRP packets is not specified. The interface where the VRRP group resides sends and receives VRRP packets.

6. Enable TTL check for IPv4 VRRP packets.

   vrrp check-ttl enable

   By default, TTL check for IPv4 VRRP packets is enabled.

7. Return to system view.

   quit

8. Set a DSCP value for VRRP packets.

   vrrp dscp *dscp-value*

   By default, the DSCP value for VRRP packets is 48.

   The DSCP value identifies the packet priority during transmission.

Configuring VF tracking

About this task

You can configure VF tracking in both standard mode and load balancing mode, but the function takes effect only in load balancing mode.

In load balancing mode, you can establish the collaboration between the VFs and NQA or BFD through the tracking function. When the state of the track entry transits to Negative, the weights of all VFs in the VRRP group on the router decrease by a specific value. When the state of the track entry transits to Positive or Notready, the original weight values of the VFs restore.

Restrictions and guidelines

- By default, the weight of a VF is 255, and its lower limit of failure is 10.
- When the weight of a VF owner is higher than or equal to the lower limit of failure, its priority is always 255. The priority does not change with the weight. When the upstream link of the VF owner fails, an LVF must take over as the AVF. The switchover happens when the weight of the VF owner drops below the lower limit of failure. This requires that the reduced weight for the VF owner be higher than 245.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the VFs in a VRRP group to monitor a track entry.

   vrrp vrid *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }

   By default, no track entry is specified.

Setting the packet sending mode for IPv4 VRRPv3

About this task

A router configured with VRRPv3 can process incoming VRRPv2 packets, but a router configured with VRRPv2 cannot process incoming VRRPv3 packets. When the VRRP version of the routers in a VRRP group is changed from VRRPv2 to VRRPv3, multiple masters might be elected in the VRRP group. To resolve the problem, you can set the packet sending mode for IPv4 VRRPv3. This task enables a router configured with VRRPv3 to send VRRPv2 packets and communicate with routers configured with VRRPv2.

Restrictions and guidelines

- The packet sending mode for IPv4 VRRPv3 takes effect only on outgoing VRRP packets. A router configured with VRRPv3 can process incoming VRRPv2 and VRRPv3 packets.
- If you set the packet sending mode for IPv4 VRRPv3 and configure VRRP packet authentication, authentication information will be carried in outgoing VRRPv2 packets but not in outgoing VRRPv3 packets.
- The VRRP advertisement interval is set in centiseconds by using the **vrrp vrid timer advertise** command. The VRRP advertisement interval carried in VRRPv2 packets sent from routers configured with VRRPv3 might be different from the configured value. For information about the VRRP advertisement interval, see the **vrrp vrid timer advertise** command in *High Availability Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the packet sending mode for IPv4 VRRPv3.
   vrrp vrid *virtual-router-id* **vrrpv3-send-packet** { **v2-only** | **v2v3-both** }
   By default, a router configured with VRRPv3 sends only VRRPv3 packets.

Enabling periodic sending of gratuitous ARP packets for IPv4 VRRP

About this task

This feature enables the master router in a VRRP group to periodically send gratuitous ARP packets. Then the downstream devices can update the MAC address entry for the virtual MAC address of the VRRP group in a timely manner.

Restrictions and guidelines

- This feature takes effect only in VRRP standard mode.
- If you change the sending interval for gratuitous ARP packets, the configuration takes effect at the next sending interval.
- The master sends the first gratuitous ARP packet at a random time in the second half of the set interval after you execute the **vrrp send-gratuitous-arp** command. This prevents too many gratuitous ARP packets from being sent at the same time.
- The sending interval for gratuitous ARP packets might be much longer than the set interval when the following conditions are met:
  - Multiple VRRP groups exist on the device.
  - A short sending interval is set.

Procedure

1. Enter system view.
   system-view
2. Enable periodic sending of gratuitous ARP packets for IPv4 VRRP.
   vrrp send-gratuitous-arp [**interval** *interval*]
   By default, periodic sending of gratuitous ARP packets is disabled for IPv4 VRRP.

Configuring a subordinate IPv4 VRRP group to follow a master IPv4 VRRP group

About this task

Each VRRP group determines the device role (master or backup) by exchanging VRRP packets among member devices, which might consume excessive bandwidth and CPU resources. To reduce the number of VRRP packets in the network, you can configure a subordinate VRRP group to follow a master VRRP group.

A master VRRP group determines the device role through exchanging VRRP packets among member devices. A VRRP group that follows a master group, called a subordinate VRRP group,

does not exchange VRRP packets among its member devices. The state of the subordinate VRRP group follows the state of the master group.

Restrictions and guidelines

- To ensure the master router election, configure the settings such as the router priority, preemptive mode, and tracking function for the master IPv4 VRRP group. The settings are not required for subordinate IPv4 VRRP groups.
- You can configure a subordinate VRRP group to follow a master VRRP group in both VRRP standard and load balancing modes. The configuration takes effect only in VRRP standard mode.
- An IPv4 VRRP group cannot be both a master group and a subordinate group.
- An IPv4 VRRP group stays in **Inactive** state if it is configured to follow a nonexistent master group.
- If an IPv4 VRRP group in **Inactive** or **Initialize** state follows a master group that is not in **Inactive** state, the state of the VRRP group does not change.
- A subordinate IPv4 VRRP group does not exchange VRRP packets, which might cause the MAC address entry for its virtual MAC address not to be updated on downstream devices. As a best practice, enable periodic sending of gratuitous ARP packets for IPv4 VRRP by using the **vrrp send-gratuitous-arp** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an IPv4 VRRP group as a master group and assign a name to it.
   vrrp vrid *virtual-router-id* **name** *name*
   By default, an IPv4 VRRP group does not act as a master group.
4. Return to system view.
   quit
5. Enter interface view.
   interface *interface-type interface-number*
6. Configure an IPv4 VRRP group to follow a master group.
   vrrp vrid *virtual-router-id* **follow** *name*
   By default, an IPv4 VRRP group does not follow a master VRRP group.

Enabling SNMP notifications for VRRP

About this task

To report critical VRRP events to an NMS, enable SNMP notifications for VRRP. For VRRP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for VRRP.
   snmp-agent trap enable vrrp [**auth-failure** | **new-master**]

By default, SNMP notifications for VRRP are enabled.

Display and maintenance commands for IPv4 VRRP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display states of IPv4 VRRP groups.	**display vrrp** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]] [**verbose**]
Display master-to-subordinate IPv4 VRRP group bindings.	**display vrrp binding** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*] | **name** *name*]
Display statistics for IPv4 VRRP groups.	**display vrrp statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]
Clear statistics for IPv4 VRRP groups.	**reset vrrp statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]

Configuring IPv6 VRRP

Restrictions and guidelines: IPv6 VRRP configuration

Configuration on the routers in an IPv6 VRRP group must be consistent.

Each IPv6 VRRP group corresponds to a virtual MAC address. The maximum number of IPv6 VRRP groups supported on an interface depends on the maximum number of virtual MAC addresses supported on the interface.

IPv6 VRRP tasks at a glance

To configure IPv6 VRRP, perform the following tasks:

1. Specifying an IPv6 VRRP operating mode
2. Configuring an IPv6 VRRP group
3. (Optional.) Configuring VF tracking

   This configuration takes effect only in VRRP load balancing mode.
4. (Optional.) Configuring IPv6 VRRP packet attributes
5. (Optional.) Enabling periodic sending of ND packets for IPv6 VRRP
6. (Optional.) Configuring a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group

Specifying an IPv6 VRRP operating mode

Restrictions and guidelines

After the IPv6 VRRP operating mode is specified on a router, all IPv6 VRRP groups on the router operate in the specified operating mode.

Procedure

1. Enter system view.
   system-view
2. Specify an IPv6 VRRP operating mode.
   - Specify the standard mode.
     undo vrrp ipv6 mode
   - Specify the load balancing mode.
     vrrp ipv6 mode load-balance

   By default, VRRP operates in standard mode.

Configuring an IPv6 VRRP group

About this task

A VRRP group can work correctly after you create it and assign a minimum of one virtual IPv6 address for it. You can configure multiple virtual IPv6 addresses for the VRRP group on an interface that connects to multiple subnets for router backup.

If you disable an IPv6 VRRP group, the VRRP group enters **Initialize** state, and the existing configuration on the VRRP group remains unchanged. You can modify the configuration of the VRRP group. The modification takes effect when you enable the VRRP group again.

Restrictions and guidelines

Item	Remarks
VLAN interface	Do not create VRRP groups on the VLAN interface of a super VLAN. Otherwise, network performance might be adversely affected. For information about the super VLAN feature, see *Layer 2—LAN Switching Configuration Guide*.
Maximum number of VRRP groups and virtual IPv6 addresses	In VRRP load balancing mode, the device supports a maximum of *MaxVRNum/N* VRRP groups. *MaxVRNum* refers to the maximum number of VRRP groups supported by the device in VRRP standard mode. *N* refers to the number of devices in the VRRP group.
Virtual IPv6 address	In load balancing mode, the virtual IPv6 address of a VRRP group cannot be the same as the IPv6 address of any interfaces in the VRRP group. No IP address owner can exist in a VRRP group. An IPv6 VRRP group without virtual IPv6 addresses configured can exist on a device provided that other settings (for example, priority and preemption mode) are available. Such a VRRP group stays in inactive state and does not function. For hosts in the subnet to access external networks, as a best practice, configure the following addresses in the same subnet: • Virtual IPv6 address of an IPv6 VRRP group. • Downlink interface IPv6 addresses of the VRRP group members.
IP address owner	On an IP address owner, as a best practice, do not use the **ospfv3 area** command to enable OSPF on the interface owning the virtual IPv6 address of the VRRP group. For more information about the **ospfv3 area** command, see *Layer 3—IP Routing Command Reference*. After you remove the IPv6 VRRP group on an IP address owner, a backup in the IPv6 VRRP group takes over as the master. The actual IPv6 address of the interface on the IP address owner will conflict with the virtual IPv6 address of the new master. To avoid the conflict, change the IPv6 address of the interface on the IP address owner

Item	Remarks
	before you remove the IPv6 VRRP group from the interface. The running priority of an IP address owner is always 255, and you do not need to configure it. An IP address owner always operates in preemptive mode. If you configure the **vrrp ipv6 vrid track priority reduced** or **vrrp ipv6 vrid track switchover** command on an IP address owner, the configuration does not take effect until the router becomes a non-IP address owner. On an IP address owner, disable Duplicate Address Detection (DAD) on the interface configured with VRRP. To disable DAD, set the *interval* argument to 0 for the **ipv6 nd dad attempts** command. For more information about the command, see IPv6 basics commands in *Layer 3—IP Services Command Reference*.
VRRP association with a track entry	When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority or the failed master router becomes the master again.

Creating a VRRP group and assign a virtual IPv6 address

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Create a VRRP group and assign a virtual IPv6 address, which is a link-local address.

   vrrp ipv6 vrid *virtual-router-id* **virtual-ip** *virtual-address* **link-local**

   The first virtual IPv6 address that you assign to an IPv6 VRRP group must be a link-local address. It must be the last address you remove. Only one link-local address is allowed in a VRRP group.

Configuring an IPv6 VRRP group

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Assign a virtual IPv6 address, which is a global unicast address.

   vrrp ipv6 vrid *virtual-router-id* **virtual-ip** *virtual-address*

   By default, no global unicast address is assigned to an IPv6 VRRP group.
4. Set the priority of the router in the VRRP group.

   vrrp ipv6 vrid *virtual-router-id* **priority** *priority-value*

   The default setting is 100.
5. Enable the preemptive mode for the router in a VRRP group and set the preemption delay time.

   vrrp ipv6 vrid *virtual-router-id* **preempt-mode** [**delay** *delay-value*]

   By default, the router in a VRRP group operates in preemptive mode and the preemption delay time is 0 centiseconds, which means an immediate preemption.
6. Associate a VRRP group with a track entry.

   vrrp ipv6 vrid *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ipv6-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }

By default, a VRRP group is not associated with any track entries.

Disabling an IPv6 VRRP group

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Disable an IPv6 VRRP group.

   vrrp ipv6 vrid *virtual-router-id* **shutdown**

   By default, an IPv6 VRRP group is enabled.

CAUTION:

You can use this command to temporarily disable an IPv6 VRRP group. After you execute this command, packets sent to the IPv6 VRRP group might be discarded.

Configuring VF tracking

About this task

You can configure VF tracking in both standard mode and load balancing mode, but the function takes effect only in load balancing mode.

In load balancing mode, you can configure the VFs in a VRRP group to monitor a track entry. When the state of the track entry transits to Negative, the weights of all VFs in the VRRP group on the router decrease by a specific value. When the state of the track entry transits to Positive or Notready, the original weights of the VFs restore.

Restrictions and guidelines

- By default, the weight of a VF is 255, and its lower limit of failure is 10.
- When the weight of a VF owner is higher than or equal to the lower limit of failure, its priority is always 255. The priority does not change with the weight. When the upstream link of the VF owner fails, an LVF must take over as the AVF. The switchover happens when the weight of the VF owner drops below the lower limit of failure. This requires that the reduced weight for the VF owner be higher than 245.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the VFs in a VRRP group to monitor a track entry.

   vrrp ipv6 vrid *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ipv6-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }

   By default, no track entry is specified.

Configuring IPv6 VRRP packet attributes

Restrictions and guidelines

- The routers in an IPv6 VRRP group can have different intervals for sending VRRP advertisements. The master in the VRRP group sends VRRP advertisements at the specified

interval and carries the interval attribute in the advertisements. After a backup receives the advertisement, it records the interval in the advertisement. If the backup does not receive a VRRP advertisement before the timer (3 x recorded interval + Skew_Time) expires, it regards the master as failed and takes over.

- A high volume of network traffic might cause a backup to fail to receive VRRP advertisements from the master within the specified time. As a result, an unexpected master switchover occurs. To solve this problem, configure a larger interval.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the IPv6 VRRP advertisement interval.

   vrrp ipv6 vrid *virtual-router-id* **timer advertise** *adver-interval*

   The default setting is 100 centiseconds.

   As a best practice to maintain system stability, set the VRRP advertisement interval to be greater than 100 centiseconds.

4. Return to system view.

   quit

5. Set a DSCP value for IPv6 VRRP packets.

   vrrp ipv6 dscp *dscp-value*

   By default, the DSCP value for IPv6 VRRP packets is 56.

   The DSCP value identifies the packet priority during transmission.

Enabling periodic sending of ND packets for IPv6 VRRP

About this task

This feature enables the master router in an IPv6 VRRP group to periodically send ND packets. Then the downstream devices can update the MAC address entry for the virtual MAC address of the IPv6 VRRP group in a timely manner.

Restrictions and guidelines

- This feature takes effect only in VRRP standard mode.
- If you change the sending interval for ND packets, the configuration takes effect at the next sending interval.
- The master sends the first ND packet at a random time in the second half of the set interval after you execute the **vrrp ipv6 send-nd** command. This prevents too many ND packets from being sent at the same time.
- The sending interval for ND packets might be much longer than the set interval when the following conditions are met:
  - Multiple IPv6 VRRP groups exist on the device.
  - A short sending interval is set.

Procedure

1. Enter system view.

   system-view

2. Enable periodic sending of ND packets for IPv6 VRRP.

   vrrp ipv6 send-nd [**interval** *interval*]

By default, periodic sending of ND packets is disabled for IPv6 VRRP.

Configuring a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group

About this task

Each IPv6 VRRP group determines the device role (master or backup) by exchanging VRRP packets among member devices, which might consume excessive bandwidth and CPU resources. To reduce the number of VRRP packets in the network, you can configure a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group.

A master IPv6 VRRP group determines the device role through exchanging VRRP packets among member devices. An IPv6 VRRP group that follows a master group, called a subordinate VRRP group, does not exchange VRRP packets among its member devices. The state of the subordinate VRRP group follows the state of the master group.

Restrictions and guidelines

- To ensure the master router election, configure the settings such as the router priority, preemptive mode, and tracking function for the master IPv6 VRRP group. The settings are not required for subordinate IPv6 VRRP groups.
- You can configure a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group in both VRRP standard and load balancing modes. The configuration takes effect only in VRRP standard mode.
- An IPv6 VRRP group cannot be both a master group and a subordinate group.
- An IPv6 VRRP group stays in **Inactive** state if it is configured to follow a nonexistent master IPv6 VRRP group.
- If an IPv6 VRRP group in **Inactive** or **Initialize** state follows a master group that is not in **Inactive** state, the state of the VRRP group does not change.
- A subordinate IPv6 VRRP group does not exchange VRRP packets, which might cause the MAC address entry for its virtual MAC address not to be updated on downstream devices. As a best practice, enable periodic sending of ND packets for IPv6 VRRP by using the **vrrp ipv6 send-nd** command.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure an IPv6 VRRP group as a master group and assign a name to it.

   vrrp ipv6 vrid *virtual-router-id* **name** *name*

   By default, an IPv6 VRRP group does not act as a master group.
4. Return to system view.

   quit
5. Enter interface view.

   interface *interface-type interface-number*
6. Configure an IPv6 VRRP group to follow a master group.

   vrrp ipv6 vrid *virtual-router-id* **follow** *name*

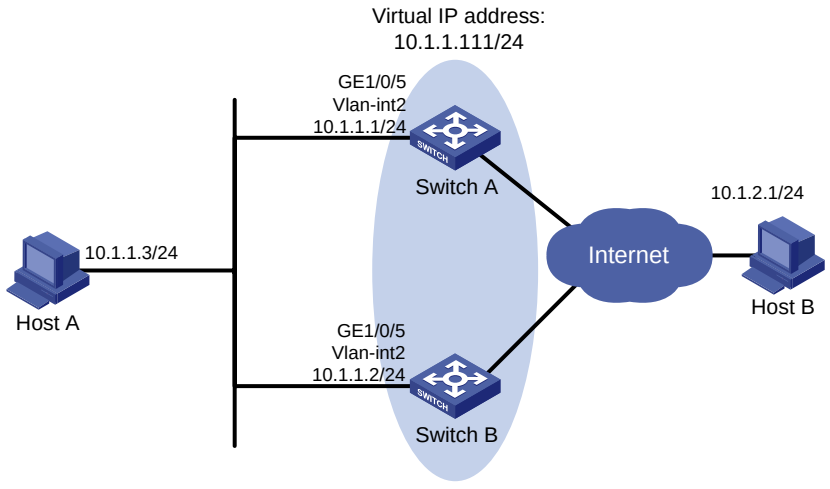
   By default, an IPv6 VRRP group does not follow a master VRRP group.

Display and maintenance commands for IPv6 VRRP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display the states of IPv6 VRRP groups.	**display vrrp ipv6** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]] [**verbose**]
Display master-to-subordinate IPv6 VRRP group bindings.	**display vrrp ipv6 binding** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*] | **name** *name*]
Display statistics for IPv6 VRRP groups.	**display vrrp ipv6 statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]
Clear statistics for IPv6 VRRP groups.	**reset vrrp ipv6 statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]

IPv4 VRRP configuration examples



Example: Configuring a single VRRP group

Network configuration

As shown in Figure 9, Switch A and Switch B form a VRRP group. They use the virtual IP address 10.1.1.111/24 to provide gateway service for the subnet where Host A resides.

Switch A operates as the master to forward packets from Host A to Host B. When Switch A fails, Switch B takes over to forward packets for Host A.

Figure 9 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 10.1.1.1 255.255.255.0
```

Create VRRP group 1 on VLAN-interface 2, and set its virtual IP address to 10.1.1.111.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.111
```

Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-Vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.1.1.2 255.255.255.0
```

Create VRRP group 1 on VLAN-interface 2, and set its virtual IP address to 10.1.1.111.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.111
```

Set the priority of Router B to 100 in VRRP group 1.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 priority 100
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
```

Verifying the configuration

Ping Host B from Host A. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:
 Running Mode      : Standard
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1                 Adver Timer  : 100
     Admin Status     : Up                State        : Master
     Config Pri       : 110               Running Pri  : 110
     Preempt Mode     : Yes               Delay Time   : 5000
     Auth Type        : Not supported
     Version          : 3
     Virtual IP       : 10.1.1.111
     Virtual MAC      : 0000-5e00-0101
     Master IP        : 10.1.1.1
```

Display detailed information about VRRP group 1 on Switch B.

```
[SwitchB-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:
 Running Mode      : Standard
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1                  Adver Timer  : 100
     Admin Status     : Up                 State        : Backup
     Config Pri       : 100                Running Pri  : 100
     Preempt Mode     : Yes                Delay Time   : 5000
     Become Master    : 401ms left
     Auth Type        : Not supported
     Version          : 3
     Virtual IP       : 10.1.1.111
     Master IP        : 10.1.1.1
```

The output shows that Switch A is operating as the master in VRRP group 1 to forward packets from Host A to Host B.

Disconnect the link between Host A and Switch A, and verify that Host A can still ping Host B. (Details not shown.)

Display detailed information about VRRP group 1 on Switch B.

```
[SwitchB-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:
 Running Mode      : Standard
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1                  Adver Timer  : 100
     Admin Status     : Up                 State        : Master
     Config Pri       : 100                Running Pri  : 100
     Preempt Mode     : Yes                Delay Time   : 5000
     Auth Type        : Not supported
     Version          : 3
     Virtual IP       : 10.1.1.111
     Virtual MAC      : 0000-5e00-0101
     Master IP        : 10.1.1.2
```

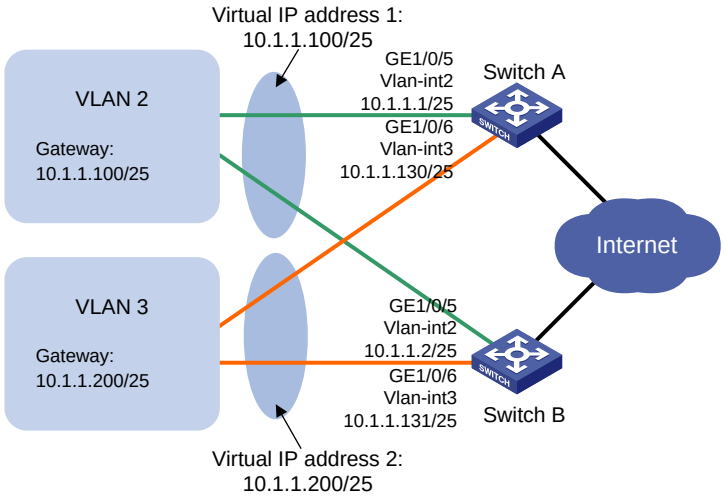
The output shows that when Switch A fails, Switch B takes over to forward packets from Host A to Host B.

Recover the link between Host A and Switch A, and display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:
 Running Mode      : Standard
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1                  Adver Timer  : 100
     Admin Status     : Up                 State        : Master
     Config Pri       : 110                Running Pri  : 110
     Preempt Mode     : Yes                Delay Time   : 5000
     Auth Type        : Not supported
```

```
Version           : 3
Virtual IP        : 10.1.1.111
Virtual MAC       : 0000-5e00-0101
Master IP         : 10.1.1.1
```

The output shows that after Switch A resumes normal operation, it becomes the master to forward packets from Host A to Host B.



Example: Configuring multiple VRRP groups

Network configuration

As shown in Figure 10, Switch A and Switch B form two VRRP groups. VRRP group 1 uses the virtual IP address 10.1.1.100/25 to provide gateway service for hosts in VLAN 2, and VRRP group 2 uses the virtual IP address 10.1.1.200/25 to provide gateway service for hosts in VLAN 3.

Assign a higher priority to Switch A than Switch B in VRRP group 1, but a lower priority in VRRP group 2. Traffic from VLAN 2 and VLAN 3 can then be distributed between the two switches. When one of the switches fails, the healthy switch provides gateway service for both VLANs.

Figure 10 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.1 255.255.255.128
   ```

   # Create VRRP group 1, and set its virtual IP address to 10.1.1.100.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.100
   ```

   # Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master in the group.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   [SwitchA-Vlan-interface2] quit
   ```

   # Configure VLAN 3.

```
[SwitchA] vlan 3
[SwitchA-vlan3] port gigabitethernet 1/0/6
[SwitchA-vlan3] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ip address 10.1.1.130 255.255.255.128
```

Create VRRP group 2, and set its virtual IP address to 10.1.1.200.

```
[SwitchA-Vlan-interface3] vrrp vrid 2 virtual-ip 10.1.1.200
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.1.1.2 255.255.255.128
```

Create VRRP group 1, and set its virtual IP address to 10.1.1.100.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.100
[SwitchB-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/6
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ip address 10.1.1.131 255.255.255.128
```

Create VRRP group 2, and set its virtual IP address to 10.1.1.200.

```
[SwitchB-Vlan-interface3] vrrp vrid 2 virtual-ip 10.1.1.200
```

Assign Switch B a higher priority than Switch A in VRRP group 2, so Switch B can become the master in the group.

```
[SwitchB-Vlan-interface3] vrrp vrid 2 priority 110
```

Verifying the configuration

Display detailed information about the VRRP groups on Switch A.

```

     Master IP         : 10.1.1.131
```

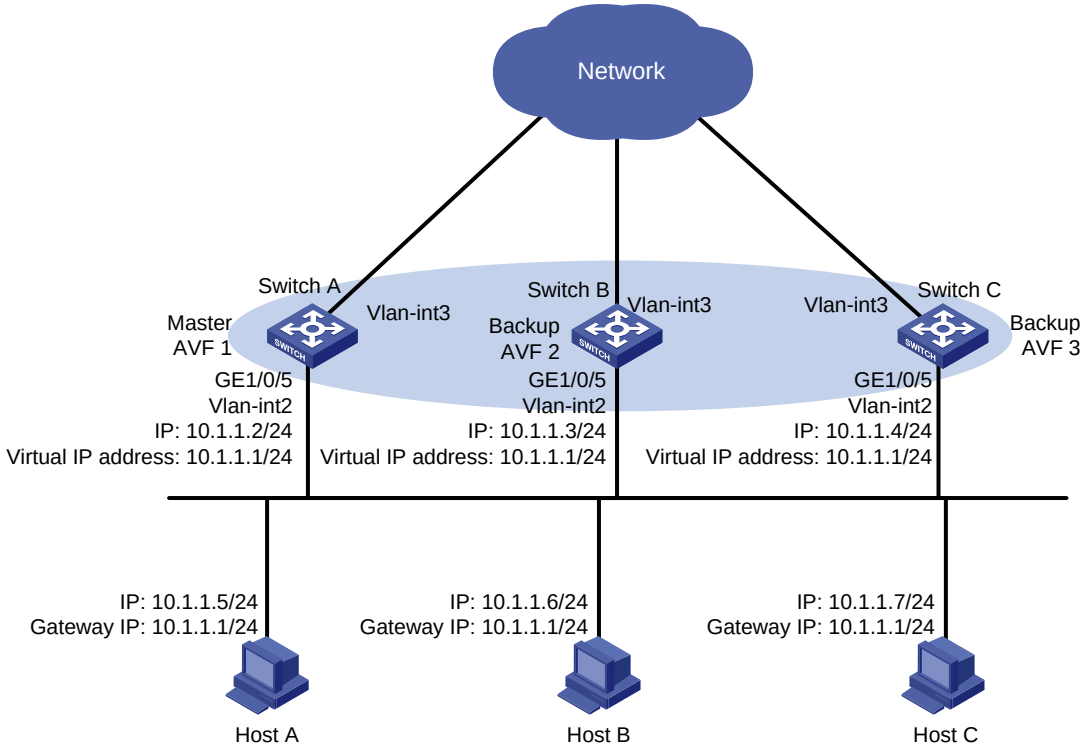
The output shows the following information:

- Switch A is operating as the master in VRRP group 1 to forward Internet traffic for hosts that use the default gateway 10.1.1.100/25.
- Switch B is operating as the master in VRRP group 2 to forward Internet traffic for hosts that use the default gateway 10.1.1.200/25.



Example: Configuring VRRP load balancing

Network configuration

As shown in Figure 11, Switch A, Switch B, and Switch C form a load-balanced VRRP group. They use the virtual IP address 10.1.1.1/24 to provide gateway service for subnet 10.1.1.0/24.

Configure VFs on Switch A, Switch B, and Switch C to monitor their respective VLAN-interface 3. When the interface on any one of them fails, the weights of the VFs on the problematic switch decrease so another AVF can take over.

Figure 11 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   ```

   # Configure VRRP to operate in load balancing mode.

   ```
   [SwitchA] vrrp mode load-balance
   ```

   # Create VRRP group 1, and set its virtual IP address to 10.1.1.1.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.2 24
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
   ```

   # Assign Switch A the highest priority in VRRP group 1, so Switch A can become the master.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 120
   ```

   # Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
   [SwitchA-Vlan-interface2] quit
   ```

   # Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchA] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 weight reduced 250
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchB] vrrp mode load-balance
```

Create VRRP group 1, and set its virtual IP address to 10.1.1.1.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.1.1.3 24
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
```

Assign Switch B a higher priority than Switch C in VRRP group 1, so Switch B can become the master when Switch A fails.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 priority 110
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
[SwitchB-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchB] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 track 1 weight reduced 250
```

3. Configure Switch C:

Configure VLAN 2.

```
<SwitchC> system-view
[SwitchC] vlan 2
[SwitchC-vlan2] port gigabitethernet 1/0/5
[SwitchC-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchC] vrrp mode load-balance
```

Create VRRP group 1, and set its virtual IP address to 10.1.1.1.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ip address 10.1.1.4 24
[SwitchC-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
```

Configure Switch C to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchC-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
[SwitchC-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchC] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] vrrp vrid 1 track 1 weight reduced 250
```

Verifying the configuration

Verify that Host A can ping the external network. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose

     Owner ID       : 0000-5e01-1103
     Priority       : 255
     Active         : local
    Forwarder 03
     State          : Listening
     Virtual MAC    : 000f-e2ff-0013 (Learnt)
     Owner ID       : 0000-5e01-1105
     Priority       : 127
     Active         : 10.1.1.4
   Forwarder Weight Track Information:
     Track Object   : 1          State : Positive   Weight Reduced : 250
```

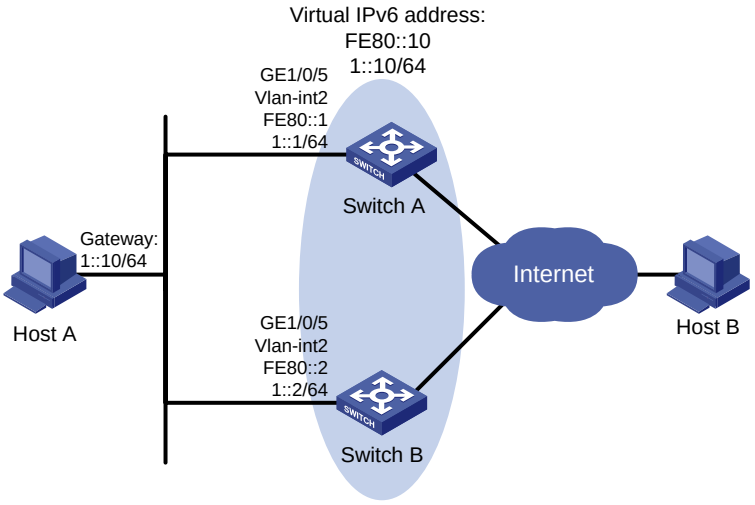
The output shows the following information:

- When Switch A fails, Switch B becomes the master because it has a higher priority than Switch C.
- The VF for virtual MAC address 000f-e2ff-0011 is removed.

IPv6 VRRP configuration examples

Example: Configuring a single VRRP group



Network configuration

As shown in Figure 12, Switch A and Switch B form a VRRP group. They use the virtual IP addresses 1::10/64 and FE80::10 to provide gateway service for the subnet where Host A resides.

Host A learns 1::10/64 as its default gateway from RA messages sent by the switches.

Switch A operates as the master to forward packets from Host A to Host B. When Switch A fails, Switch B takes over to forward packets for Host A.

Figure 12 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
   [SwitchA-Vlan-interface2] ipv6 address 1::1 64
   ```

   # Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
   ```

   # Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
   ```

   # Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
   ```

   # Enable Switch A to send RA messages, so Host A can learn the default gateway address.

   ```
   [SwitchA-Vlan-interface2] undo ipv6 nd ra halt
   ```

2. Configure Switch B:

   # Configure VLAN 2.

   ```
   <SwitchB> system-view
   [SwitchB] vlan 2
   [SwitchB-vlan2] port gigabitethernet 1/0/5
   [SwitchB-vlan2] quit
   ```

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
```

Create VRRP group 1 and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch B to send RA messages, so Host A can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
```

Verifying the configuration

Ping Host B from Host A. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose

     Admin Status     : Up                 State        : Master
     Config Pri       : 110                Running Pri  : 110
     Preempt Mode     : Yes                Delay Time   : 5000
     Auth Type        : None
     Virtual IP       : FE80::10
                        1::10
     Virtual MAC      : 0000-5e00-0201
     Master IP        : FE80::1
```

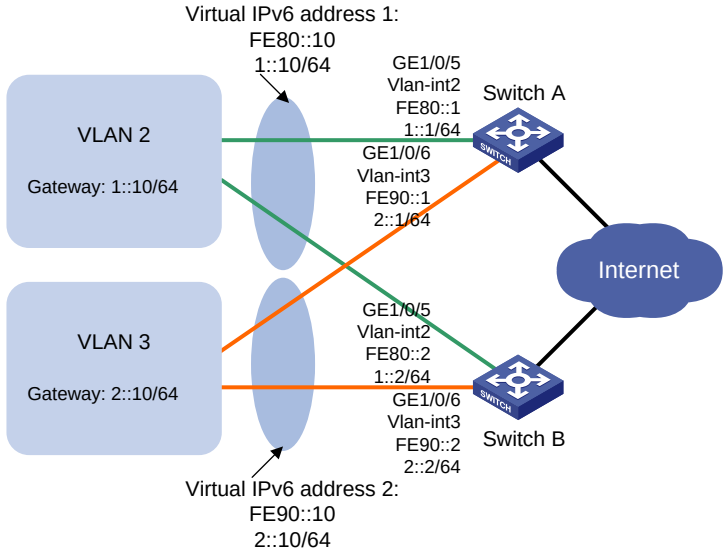
The output shows that after Switch A resumes normal operation, it becomes the master to forward packets from Host A to Host B.

Example: Configuring multiple VRRP groups



Network configuration

As shown in Figure 13, Switch A and Switch B form two VRRP groups. VRRP group 1 uses the virtual IPv6 addresses 1::10/64 and FE80::10 to provide gateway service for hosts in VLAN 2. VRRP group 2 uses the virtual IPv6 addresses 2::10/64 and FE90::10 to provide gateway service for hosts in VLAN 3.

From RA messages sent by the switches, hosts in VLAN 2 learn 1::10/64 as their default gateway. Hosts in VLAN 3 learn 2::10/64 as their default gateway.

Assign Switch A a higher priority than Switch B in VRRP group 1 but a lower priority in VRRP group 2. Traffic from VLAN 2 and VLAN 3 can then be distributed between the two switches. When one of the switches fails, the healthy switch provides gateway service for both VLANs.

Figure 13 Network diagram

Procedure

1. Configure Switch A:

Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
[SwitchA-Vlan-interface2] ipv6 address 1::1 64
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 to 1::10.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master in the group.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
```

Enable Switch A to send RA messages, so hosts in VLAN 2 can learn the default gateway address.

```
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
[SwitchA-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchA] vlan 3
[SwitchA-vlan3] port gigabitethernet 1/0/6
[SwitchA-vlan3] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ipv6 address fe90::1 link-local
[SwitchA-Vlan-interface3] ipv6 address 2::1 64
```

Create VRRP group 2, and set its virtual IPv6 addresses to FE90::10 and 2::10.

```
[SwitchA-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip fe90::10 link-local
[SwitchA-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip 2::10
```

Enable Switch A to send RA messages, so hosts in VLAN 3 can learn the default gateway address.

```
[SwitchA-Vlan-interface3] undo ipv6 nd ra halt
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Enable Switch B to send RA messages, so hosts in VLAN 2 can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
[SwitchB-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/6
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ipv6 address fe90::2 link-local
[SwitchB-Vlan-interface3] ipv6 address 2::2 64
```

Create VRRP group 2, and set its virtual IPv6 addresses to FE90::10 and 2::10.

```
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip fe90::10 link-local
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip 2::10
```

Assign Switch B a higher priority than Switch A in VRRP group 2, so Switch B can become the master in the group.

```
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 priority 110
```

Enable Switch B to send RA messages, so hosts in VLAN 3 can learn the default gateway address.

```
[SwitchB-Vlan-interface3] undo ipv6 nd ra halt
```

Verifying the configuration

Display detailed information about the VRRP groups on Switch A.

```
[SwitchA-Vlan-interface3] display vrrp ipv6 verbose

```

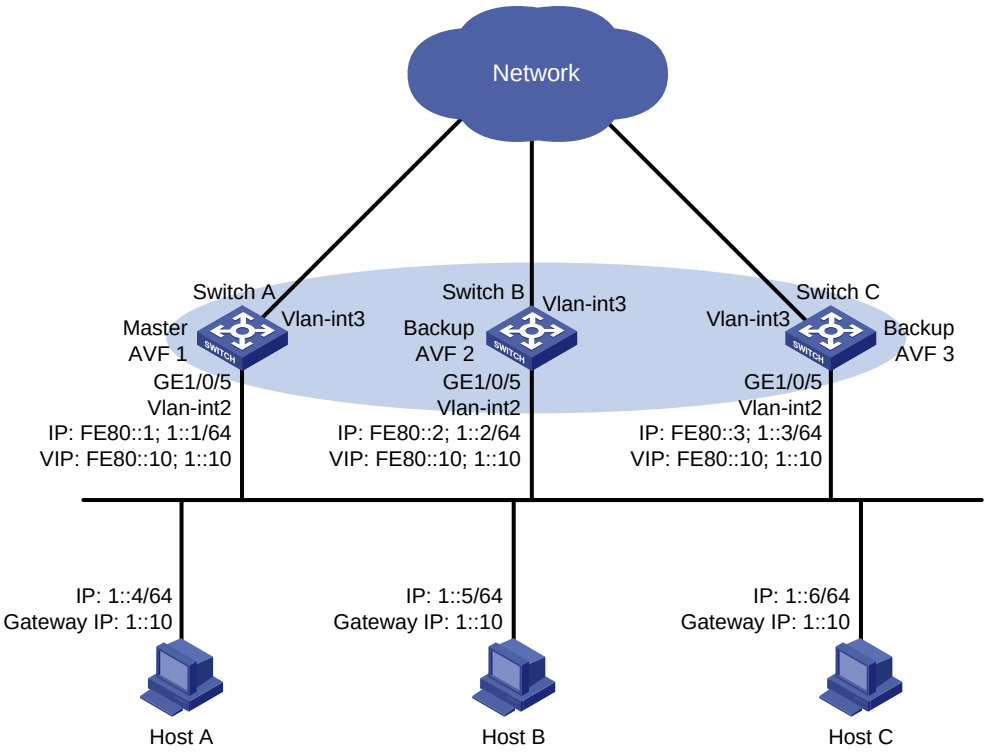
The output shows the following information:

- Switch A is operating as the master in VRRP group 1 to forward Internet traffic for hosts that use the default gateway 1::10/64.
- Switch B is operating as the master in VRRP group 2 to forward Internet traffic for hosts that use the default gateway 2::10/64.

Example: Configuring VRRP load balancing



Network configuration

As shown in Figure 14, Switch A, Switch B, and Switch C form a load balanced VRRP group. They use the virtual IPv6 addresses FE80::10 and 1::10 to provide gateway service for subnet 1::/64.

Hosts on subnet 1::/64 learn 1::10 as their default gateway from RA messages sent by the switches.

Configure VFs on Switch A, Switch B, or Switch C to monitor their respective VLAN-interface 3. When the interface on any of them fails, the weights of the VFs on the problematic switch decrease so another AVF can take over.

Figure 14 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   ```

   # Configure VRRP to operate in load balancing mode.

   ```
   [SwitchA] vrrp ipv6 mode load-balance
   ```

   # Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
   [SwitchA-Vlan-interface2] ipv6 address 1::1 64
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
   ```

Assign Switch A the highest priority in VRRP group 1, so Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 120
```

Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch A to send RA messages, so hosts on subnet 1::/64 can learn the default gateway address.

```
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
[SwitchA-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchA] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 track 1 weight reduced 250
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchB] vrrp ipv6 mode load-balance
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Assign Switch B a higher priority than Switch C in VRRP group 1, so Switch B can become the master when Switch A fails.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch B to send RA messages so hosts on subnet 1::/64 can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
[SwitchB-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchB] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 track 1 weight reduced 250
```

3. Configure Switch C:

Configure VLAN 2.

```
<SwitchC> system-view
[SwitchC] vlan 2
[SwitchC-vlan2] port gigabitethernet 1/0/5
[SwitchC-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchC] vrrp ipv6 mode load-balance
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ipv6 address fe80::3 link-local
[SwitchC-Vlan-interface2] ipv6 address 1::3 64
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Configure Switch C to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch C to send RA messages, so the hosts on the subnet 1::/64 can learn the default gateway address.

```
[SwitchC-Vlan-interface2] undo ipv6 nd ra halt
[SwitchC-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchC] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 track 1 weight reduced 250
```

Verifying the configuration

Verify that Host A can ping the external network. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose

    Preempt Mode     : Yes                  Delay Time   : 5000
    Become Master    : 400ms left
    Auth Type        : None
    Virtual IP       : FE80::10
                       1::10
    Member IP List   : FE80::3 (Local, Backup)
                       FE80::1 (Master)
                       FE80::2 (Backup)
  Forwarder Information: 2 Forwarders 1 Active
    Config Weight  : 255
    Running Weight : 255
   Forwarder 02
    State          : Listening
    Virtual MAC    : 000f-e2ff-4012 (Learnt)
    Owner ID       : 0000-5e01-1103
    Priority       : 127
    Active         : FE80::2
   Forwarder 03
    State          : Active
    Virtual MAC    : 000f-e2ff-4013 (Owner)
    Owner ID       : 0000-5e01-1105
    Priority       : 255
    Active         : local
  Forwarder Weight Track Information:
    Track Object   : 1          State : Positive   Weight Reduced : 250
```

The output shows that when the timeout timer expires, the VF for virtual MAC address 000f-e2ff-4011 is removed. The VF no longer forwards the packets destined for the MAC address.

When Switch A fails, display detailed information about VRRP group 1 on Switch B.

```
[SwitchB-Vlan-interface2] display vrrp ipv6 verbose
IPv6 Virtual Router Information:
 Running Mode      : Load Balance
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1                    Adver Timer  : 100
     Admin Status     : Up                   State        : Master
     Config Pri       : 110                  Running Pri  : 110
     Preempt Mode     : Yes                  Delay Time   : 5000
     Auth Type        : None
     Virtual IP       : FE80::10
                        1::10
     Member IP List   : FE80::2 (Local, Master)
                        FE80::3 (Backup)
   Forwarder Information: 2 Forwarders 1 Active
     Config Weight  : 255
     Running Weight : 255
```

```
Forwarder 02
 State           : Active
 Virtual MAC     : 000f-e2ff-4012 (Owner)
 Owner ID        : 0000-5e01-1103
 Priority        : 255
 Active          : local
Forwarder 03
 State           : Listening
 Virtual MAC     : 000f-e2ff-4013 (Learnt)
 Owner ID        : 0000-5e01-1105
 Priority        : 127
 Active          : FE80::3
Forwarder Weight Track Information:
 Track Object    : 1          State : Positive   Weight Reduced : 250
```

The output shows the following information:

- When Switch A fails, Switch B becomes the master because it has a higher priority than Switch C.
- The VF for virtual MAC address 000f-e2ff-4011 is removed.

Troubleshooting VRRP

An error prompt is displayed

Symptom

An error prompt "The virtual router detected a VRRP configuration error." is displayed during configuration.

Analysis

This symptom is probably caused by the following reasons:

- The VRRP advertisement interval in the packet is not the same as that for the current VRRP group (in VRRPv2 only).
- The number of virtual IP addresses in the packet is not the same as that for the current VRRP group.
- The virtual IP address list is not the same as that for the current VRRP group.
- A device in the VRRP group receives illegitimate VRRP packets. For example, the IP address owner receives a VRRP packet with the priority 255.

Solution

To resolve the problem:

1. Modify the configuration on routers in VRRP groups to ensure consistent configuration.
2. Take fault location and anti-attack measures to eliminate potential threats.
3. If the problem persists, contact H3C Support.

Multiple masters appear in a VRRP group

Symptom

Multiple masters appear in a VRRP group.

Analysis

It is normal for a VRRP group to have multiple masters for a short time, and this situation requires no manual intervention.

If multiple masters coexist for a longer period, check for the following conditions:

- The masters cannot receive advertisements from each other.
- The received advertisements are illegitimate.

Solution

To resolve the problem:

1. Ping between these masters:
   - If the ping operation fails, examine network connectivity.
   - If the ping operation succeeds, check for configuration inconsistencies in the number of virtual IP addresses, virtual IP addresses, and authentication. For IPv4 VRRP, also make sure the same version of VRRP is configured on all routers in the VRRP group. For VRRPv2, make sure the same VRRP advertisement interval is configured on the routers in the VRRP group.
2. If the problem persists, contact H3C Support.

Fast VRRP state flapping

Symptom

Fast VRRP state flapping occurs.

Analysis

The VRRP advertisement interval is set too short.

Solution

To resolve the problem:

1. Increase the interval for sending VRRP advertisements or introduce a preemption delay.
2. If the problem persists, contact H3C Support.

Configuring BFD

About BFD

Bidirectional forwarding detection (BFD) provides a general-purpose, standard, medium- and protocol-independent fast failure detection mechanism. It can detect and monitor the connectivity of forwarding paths to detect communication failures quickly so that measures can be taken to ensure service continuity and enhance network availability.

BFD can uniformly and quickly detect the failures of the bidirectional forwarding paths between two devices for upper-layer protocols such as routing protocols. The hello mechanism used by upper-layer protocols needs seconds to detect a link failure, while BFD can provide detection measured in milliseconds.

Single-hop detection and multihop detection

BFD can be used for single-hop and multihop detections.

- **Single-hop detection**—Detects the IP connectivity between two directly connected systems.
- **Multihop detection**—Detects any of the paths between two systems. These paths have multiple hops, and might overlap.

BFD session modes

BFD sessions use echo packets and control packets.

Echo packet mode

Echo packets are encapsulated into UDP packets with port number 3785.

The local end of the link sends echo packets to establish BFD sessions and monitor link status. The peer end does not establish BFD sessions and only forwards the packets back to the originating end. If the local end does not receive echo packets from the peer end within the detection time, it considers the session to be down.

Control packet mode

Control packets are encapsulated into UDP packets with port number 3784 for single-hop detection or port number 4784 for multihop detection.

The two ends of the link negotiate the establishment of BFD sessions by using the session parameters carried in control packets. Session parameters include session discriminators, desired minimum packet sending and receiving intervals, and local BFD session state.

Both ends of the link exchange BFD control packets to monitor link status.

Before a BFD session is established, BFD has two operating modes—active and passive.

- **Active mode**—BFD actively sends BFD control packets regardless of whether any BFD control packet is received from the peer.
- **Passive mode**—BFD does not send control packets until a BFD control packet is received from the peer.

At least one end must operate in active mode for a BFD session to be established.

After a BFD session is established, the two ends can operate in the following BFD operating modes:

- **Asynchronous mode**—The device periodically sends BFD control packets. The device considers that the session is down if it does not receive any BFD control packets within a specific interval.

- **Demand mode**—The device periodically sends BFD control packets with the D bit set. If the peer end is operating in Asynchronous mode (default), the peer end stops sending BFD control packets after receiving control packets with the D bit set. In this case, BFD detects only the connectivity from the local end to the peer end. If the peer end does not receive control packets within the detection time, the session is declared to be down. If the peer end is operating in Demand mode, both ends stop sending BFD control packets. The system uses other mechanisms such as Hello mechanism and hardware detection to detect links. The Demand mode can be used to reduce the overhead when a large number of BFD sessions exist.

Supported features

Features	Reference
Static routing OSPF RIP IP fast reroute (FRR)	*Layer 3—IP Routing Configuration Guide*
IPv6 static routing OSPFv3	*Layer 3—IP Routing Configuration Guide*
Track	"Configuring Track"
Ethernet link aggregation	*Layer 2—LAN Switching Configuration Guide*

Protocols and standards

- RFC 5880, *Bidirectional Forwarding Detection (BFD)*
- RFC 5881, *Bidirectional Forwarding Detection (BFD) for IPv4 and IPv6 (Single Hop)*
- RFC 5882, *Generic Application of Bidirectional Forwarding Detection (BFD)*
- RFC 5883, *Bidirectional Forwarding Detection (BFD) for Multihop Paths*
- RFC 7130, *Bidirectional Forwarding Detection (BFD) on Link Aggregation Group (LAG) Interfaces*

Restrictions and guidelines: BFD configuration

- By default, the device runs BFD version 1 and is compatible with BFD version 0. You cannot change the BFD version to 0 through commands. When the peer device runs BFD version 0, the local device automatically switches to BFD version 0.
- After a BFD session is established, the two ends negotiate BFD parameters, including minimum sending interval, minimum receiving interval, initialization mode, and packet authentication, by exchanging negotiation packets. They use the negotiated parameters without affecting the session status.
- BFD session flapping might occur on an aggregate interface with member ports on different IRF member devices. When the master device, which receives and sends BFD packets, is removed or restarted, a subordinate device might not immediately take over. For example, a subordinate device will not take over when the subordinate device has a short detection time or a large number of BFD sessions.

Configuring BFD sessions in echo packet mode

1. Enter system view.
   system-view
2. Configure the source IP address of echo packets.
   - Configure the source IP address of echo packets.
     bfd echo-source-ip *ip-address*
     By default, no source IPv4 address is configured for echo packets.
     As a best practice, do not configure the source IPv4 address to be on the same network segment as any local interface's IPv4 address. If you configure such a source IPv4 address, a large number of ICMP redirect packets might be sent from the peer, resulting in link congestion.
   - Configure the source IPv6 address of echo packets.
     bfd echo-source-ipv6 *ipv6-address*
     By default, no source IPv6 address is configured for echo packets.
     The source IPv6 address of echo packets can only be a global unicast address.
3. (Optional.) Set the echo packet mode parameters.
   a. Enter interface view.
      interface *interface-type interface-number*
   b. Set the minimum interval for receiving BFD echo packets.
      bfd min-echo-receive-interval *interval*
      The default setting is 400 milliseconds.
   c. Set the detection time multiplier.
      bfd detect-multiplier *value*
      The default setting is 5.

Configuring BFD sessions in control packet mode

About BFD session creation methods

BFD sessions in control packet mode can be created statically or established dynamically.

BFD sessions are distinguished by the local discriminator and remote discriminator in control packets. The main difference between a statically created session and a dynamically established session is that they obtain the local discriminator and remote discriminator in different ways.

- The local discriminator and remote discriminator of a static BFD session are specified manually in the **bfd static** command or in the commands that associate specific applications with BFD.
- The local discriminator of a dynamic BFD session is assigned by the device, and the remote discriminator is obtained during BFD session negotiation. A created session without manually specified local and remote discriminators is a dynamic BFD session.

Restrictions and guidelines

After an upper-layer protocol is configured to support BFD, the device automatically creates BFD sessions in control packet mode. You do not need to perform this task.

BFD version 0 does not support the following commands:

- **bfd session init-mode**.
- **bfd authentication-mode**.
- **bfd demand enable**.
- **bfd echo enable**.

When the same BFD session (with the same source IP address, destination IP address, interface, VPN, and destination port number) is associated with multiple upper layer applications, BFD selects the detection time settings for the BFD session as follows:

1. Minimum values of the following settings:
   - Settings configured in static BFD session view.
   - Settings configured in the BFD template specified by the upper layer application.
   - Settings configured by the upper layer application.
2. Settings configured in interface view or system view.
3. Default settings.

When a BFD session is associated with only one upper layer application, BFD selects the detection time settings for the BFD session as follows:

1. BFD selects the detection time settings for the BFD session based on whether the upper layer application supports using a BFD template and configuring detection time settings:
   - If a BFD template is specified and detection time settings are also configured for the upper layer application, BFD selects the settings configured in the specified BFD template.
   - If a BFD template is specified for the upper layer application that does not support configuring detection time settings, BFD selects the settings configured in the specified BFD template.
   - If detection time settings are configured for the upper layer application that does not support using a BFD template, BFD selects the configured settings.
2. Settings configured in interface view or system view.
3. Default settings.

The **bfd demand enable** command cannot take effect when any of the following conditions exist:

- Echo-packet-mode BFD sessions exist on the device.
- SBFD sessions exist on the device.
- BFD sessions for detecting aggregate links exist on the device.
- After the **bfd detect-interface source-ip** command is configured, the **bfd detect-interface first-fail-timer** and **bfd detect-interface special-processing** commands are configured.

Configuring a static BFD session

About this task

A static BFD session can be used for single-hop detection and multihop detection. By working with Track, a static BFD session can provide fast failure detection. For more information about Track association with BFD, see "Configuring Track."

Restrictions and guidelines for static BFD session configuration

If a static BFD session is created on the remote end, the static BFD session must be created on the local end.

When creating a static BFD session, you must specify a peer IPv4 or IPv6 address. The system checks only the format of the IP address but not its correctness. If the peer IPv4 or IPv6 address is incorrect, the static BFD session cannot be established.

Different static BFD sessions cannot have the same local discriminator.

Creating a static BFD session for single-hop detection

1. Enter system view.

   system-view

2. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* **peer-ip** *ipv4-address* **interface** *interface-type interface-number* **source-ip** *ipv4-address* [**discriminator local** *local-value* **remote** *remote-value*]

   For a static BFD session to be established, specify the IPv4 address of the peer interface where the static BFD session resides for the **peer-ip** *ipv4-address* option. Specify the IPv4 address of the local interface where the static BFD session resides for the **source-ip** *ipv4-address* option.

   IPv6:

   bfd static *session-name* **peer-ipv6** *ipv6-address* **interface** *interface-type interface-number* **source-ipv6** *ipv6-address* [**discriminator local** *local-value* **remote** *remote-value*]

   For a static BFD session to be established, specify the IPv6 address of the peer interface where the static BFD session resides for the **peer-ipv6** *ipv6-address* option. Specify the IPv6 address of the local interface where the static BFD session resides for the **source-ipv6** *ipv6-address* option.

3. (Optional.) Specify the local and remote discriminators for the static BFD session.

   discriminator { **local** *local-value* | **remote** *remote-value* }

   By default, no local discriminator or remote discriminator is specified for a static BFD session.

   Use this command only if you do not specify the local or remote discriminator when creating a static BFD session.

Create a static BFD session for multihop detection

1. Enter system view.

   system-view

2. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* **peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*] **source-ip** *ipv4-address* [**discriminator local** *local-value* **remote** *remote-value* [**track-interface** *interface-type interface-number*]]

   IPv6:

   bfd static *session-name* **peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] **source-ipv6** *ipv6-address* [**discriminator local** *local-value* **remote** *remote-value* [**track-interface** *interface-type interface-number*]]

3. (Optional.) Specify the local and remote discriminators for the static BFD session.

   discriminator { **local** *local-value* | **remote** *remote-value* }

   By default, no local discriminator or remote discriminator is specified for a static BFD session.

   Use this command only if you do not specify the local or remote discriminator when creating a static BFD session.

Configuring BFD session parameters for single-hop detection

1. Enter system view.
   system-view
2. Specify the mode for establishing a BFD session.
   bfd session init-mode { **active** | **passive** }
   By default, **active** is specified.
3. Enter interface view or static BFD session view.
   - Enter interface view.
     interface *interface-type interface-number*
   - Enter static BFD session view.
     bfd static *session-name*
     The static BFD session must already exist.
4. (Optional.) Configure the authentication mode for single-hop control packets.
   bfd authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }
   By default, single-hop BFD packets are not authenticated.
5. Enable the Demand BFD session mode.
   bfd demand enable
   By default, the BFD session is in Asynchronous mode.
   This command is supported only in interface view.
6. Set the minimum interval for receiving echo packets.
   bfd min-echo-receive-interval *interval*
   The default setting is 400 milliseconds.
7. Set the minimum interval for transmitting and receiving single-hop BFD control packets.
   - Set the minimum interval for transmitting single-hop BFD control packets.
     bfd min-transmit-interval *interval*

   The default setting is 400 milliseconds.
   - Set the minimum interval for receiving single-hop BFD control packets.
     bfd min-receive-interval *interval*

   The default setting is 400 milliseconds.
8. Set the single-hop detection time multiplier.
   bfd detect-multiplier *value*
   The default setting is 5.

Configuring BFD session parameters for multihop detection

1. Enter system view.
   system-view
2. Specify the mode for establishing a BFD session.
   bfd session init-mode { **active** | **passive** }
   By default, **active** is specified.
3. (Optional.) Enter static BFD session view.

bfd static *session-name*

The static BFD session must already exist.

4. (Optional.) Configure the authentication mode for multihop BFD control packets.

   bfd multi-hop authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

   By default, no authentication is performed.

5. Configure the destination port number for multihop BFD control packets.

   bfd multi-hop destination-port *port-number*

   The default setting is 4784.

   This command is supported only in system view.

6. Set the multihop detection time multiplier.

   bfd multi-hop detect-multiplier *value*

   The default setting is 5.

7. Set the minimum interval for transmitting and receiving multihop BFD control packets.
   - Set the minimum interval for transmitting multihop BFD control packets.

     bfd multi-hop min-transmit-interval *interval*

     The default setting is 400 milliseconds.
   - Set the minimum interval for receiving multihop BFD control packets.

     bfd multi-hop min-receive-interval *interval*

   The default setting is 400 milliseconds.

Enabling the echo function

About this task

This function enables the local system to periodically send echo packets to the remote system. The remote system loops back the echo packets to the local system without processing them. If the local system does not receive the looped-back echo packets, it declares the BFD session down.

This function is supported only for single-hop detection.

Restrictions and guidelines

This function does not take effect on BFD sessions associated with interface states.

Procedure

1. Enter system view.

   system-view

2. Enter interface view or static BFD session view.
   - Enter interface view.

     interface *interface-type interface-number*
   - Enter static BFD session view.

     bfd static *session-name*

     The static BFD session must already exist.

3. Enable the echo function.

   bfd echo [**receive** | **send**] **enable**

   By default, the echo function is disabled.

Associating the interface state with BFD

About this task

By creating a BFD session for single-hop detection through exchange of BFD control packets, this feature implements fast link detection. When BFD detects a link fault, it sets the link layer protocol state to DOWN(BFD). This behavior helps applications relying on the link layer protocol state achieve fast convergence. The source IP address of control packets is specified manually, and the destination IP address is fixed at 224.0.0.184. As a best practice, specify the IP address of the interface as the source IP address. If the interface does not have an IP address, specify a unicast IP address other than 0.0.0.0 as the source IP address.

- Layer 2 Ethernet interfaces.
- Member ports in a Layer 2 aggregation group.
- Layer 2 aggregate interfaces.

Restrictions and guidelines

The echo function does not take effect on BFD sessions associated with interface states.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Associate the interface state with BFD.

   bfd detect-interface source-ip *ip-address* [**discriminator local** *local-value* **remote** *remote-value*] [**template** *template-name*]

   If the peer device does not support obtaining BFD session discriminators through autonegotiation, you must specify the discriminators on both the local and peer devices. Without the discriminators, the BFD session cannot come up.
4. (Optional.) Configure the timer that delays reporting the first BFD session establishment failure to the data link layer.

   bfd detect-interface first-fail-timer *seconds*

   By default, the first BFD session establishment failure is not reported to the data link layer.
5. (Optional.) Enable special processing for BFD sessions.

   bfd detect-interface special-processing [**admin-down** | **authentication-change** | **session-up**] *

   By default, all types of special processing are disabled for BFD sessions.

Configuring BFD session flapping suppression

About this task

When BFD detects a link failure, it tears down the BFD session and notifies the upper-layer protocol of the failure. When the upper-layer protocol re-establishes a neighbor relationship, the BFD session comes up again. BFD session flaps occur when a link fails and recovers repeatedly, which consumes significant system resources and causes network instability.

This feature allows you to suppress BFD session flapping by using the *initial-interval*, *secondary-interval*, and *maximum-interval* arguments.

- A BFD session is suppressed within the specified interval. The suppression time does not exceed the *maximum-interval*.

- After a BFD session goes down for the second time, it cannot be re-established within the *initial-interval*.
- After a BFD session goes down for the third time, it cannot be re-established within the *secondary-interval*.
- After a BFD session goes down for the fourth time and at any later time, the following rules apply:
  - If *secondary-interval* × 2^{n-3} is smaller than or equal to the *maximum-interval*, the BFD session cannot be re-established within the *secondary-interval* × 2^{n-3}.
  - If *secondary-interval* × 2^{n-3} is greater than the *maximum-interval*, the BFD session cannot be re-established within the *maximum-interval*.

  The letter n, starting from 4, is the number of times the BFD session flaps.

Procedure

1. Enter system view.

   system-view
2. Configure BFD session flapping suppression.

   bfd dampening [**maximum** *maximum-interval* **initial** *initial-interval* **secondary** *secondary-interval*]

   By default, BFD sessions are not suppressed.

   The values for the *initial-interval* and *secondary-interval* arguments cannot be greater than or equal to the value for the *maximum-interval* argument.

Configuring a BFD template

About this task

This task can also be used to specify BFD parameters for BFD sessions that detect interface states.

Procedure

1. Enter system view.

   system-view
2. Create a BFD template and enter BFD template view.

   bfd template *template-name*
3. (Optional.) Configure the authentication mode for BFD control packets.

   bfd authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

   By default, no authentication is performed.
4. Set the detection time multiplier.

   bfd detect-multiplier *value*

   The default setting is 5.
5. Set the minimum interval for transmitting and receiving BFD control packets.
   - Set the minimum interval for transmitting BFD control packets.

     bfd min-transmit-interval *interval*

     The default setting is 400 milliseconds.
   - Set the minimum interval for receiving BFD control packets.

     bfd min-receive-interval *interval*

The default setting is 400 milliseconds.

Enabling SNMP notifications for BFD

About this task

To report critical BFD events to an NMS, enable SNMP notifications for BFD. For BFD event notifications to be sent correctly, you must also configure SNMP as described in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for BFD.
   snmp-agent trap enable bfd
   By default, SNMP notifications are enabled for BFD.

Display and maintenance commands for BFD

Execute the **display** command in any view and the **reset** command in user view.

Task	Command
Display BFD session information.	**display bfd session** [**discriminator local** *local-value* | **static** *session-name* | **verbose**] **display bfd session** [[**dynamic**] [**control** | **echo**] [**ip**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]] **display bfd session** [[**dynamic**] [**control** | **echo**] [**ipv6**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]] **display bfd session** [[**static**] [**ip**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**] **display bfd session** [[**static**] [**ipv6**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]
Clear BFD session statistics.	**reset bfd session statistics**

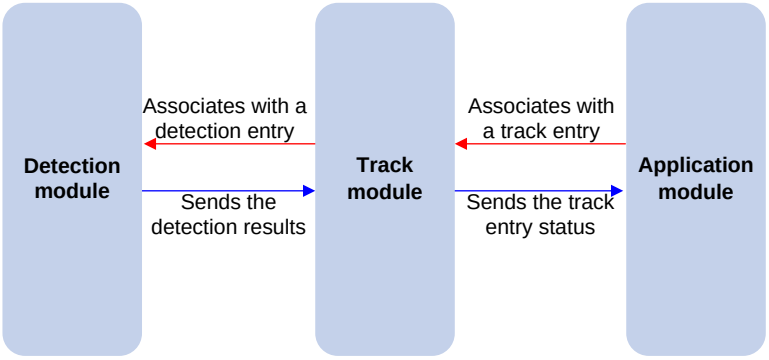
Configuring Track

About Track

The Track module works between application modules and detection modules. It shields the differences between various detection modules from application modules.



Collaboration mechanism

The Track module collaborates with detection modules and application modules.

As shown in Figure 1, collaboration is enabled when you associate the Track module with a detection module and an application module, and it operates as follows:

1. The detection module probes specific objects such as interface status, link status, network reachability, and network performance, and informs the Track module of detection results.
2. The Track module sends the detection results to the application module.
3. When notified of changes for the tracked object, the application modules can react to avoid communication interruption and network performance degradation.

Figure 1 Collaboration through the Track module

Collaboration between the Track module and a detection module

The detection module sends the detection result of the tracked object to the Track module. The Track module changes the status of the track entry as follows:

- If the tracked object operates correctly, the state of the track entry is Positive. For example, the track entry state is Positive in one of the following conditions:
  - The target interface is up.
  - The target network is reachable.
- If the tracked object does not operate correctly, the state of the track entry is Negative. For example, the track entry state is Negative in one of the following conditions:
  - The target interface is down.
  - The target network is unreachable.
- If the detection result is invalid, the state of the track entry is NotReady. For example, the track entry state is NotReady if its associated NQA operation does not exist.

Collaboration between the Track module and an application module

The track module reports the track entry status changes to the application module. The application module can then take correct actions to avoid communication interruption and network performance degradation.

Supported detection modules

The following detection modules can be associated with the Track module:

- NQA.
- BFD.
- CFD.
- Interface management.
- Route management.
- LLDP.

You can also associate a track entry with a list of objects called a tracked list. The state of a tracked list is determined by the states of all objects in the list. The following types of tracked lists are supported:

- **Boolean AND list**—The state of a Boolean AND list is determined by the states of the tracked objects using the Boolean AND operation.
- **Boolean OR list**—The state of a Boolean OR list is determined by the states of the tracked objects using the Boolean OR operation.
- **Percentage threshold list**—The state of a percentage threshold list is determined by comparing the percentage of positive objects in the list with the percentage thresholds configured for the list.
- **Weight threshold list**—The state of a weight threshold list is determined by comparing the weight of positive objects in the list with the weight thresholds configured for the list.

Supported application modules

The following application modules can be associated with the Track module:

- VRRP.
- Static routing.
- PBR
- Smart Link.
- EAA.
- ERPS.

Restrictions and guidelines: Track configuration

When configuring a track entry for an application module, you can set a notification delay to avoid immediate notification of status changes.

When the delay is not configured and the route convergence is slower than the link state change notification, communication failures occur. For example, when the master in a VRRP group detects an uplink interface failure through Track, Track immediately notifies the master to decrease its priority. A backup with a higher priority then preempts as the new master. When the failed uplink interface recovers, the Track module immediately notifies the original master to restore its priority. If the uplink route has not recovered, forwarding failure will occur.

Collaboration application example

The following is an example of collaboration between NQA, Track, and static routing.

Configure a static route with next hop 192.168.0.88 on the device. If the next hop is reachable, the static route is valid. If the next hop becomes unreachable, the static route is invalid. For this purpose, configure NQA-Track-static routing collaboration as follows:

1. Create an NQA operation to monitor the accessibility of IP address 192.168.0.88.
2. Create a track entry and associate it with the NQA operation.
   - When next hop 192.168.0.88 is reachable, NQA sends the result to the Track module. The Track module sets the track entry to Positive state.
   - When the next hop becomes unreachable, NQA sends the result to the Track module. The Track module sets the track entry to Negative state.
3. Associate the track entry with the static route.
   - When the track entry is in Positive state, the static routing module considers the static route to be valid.
   - When the track entry is in Negative state, the static routing module considers the static route to be invalid.

Track tasks at a glance

To implement the collaboration function, establish associations between the Track module and detection modules, and between the Track module and application modules.

To configure the Track module, perform the following tasks:

1. Associating the Track module with a detection module
   - Associating Track with NQA
   - Associating Track with BFD
   - Associating Track with CFD
   - Associating Track with interface management
   - Associating Track with route management
   - Associating Track with LLDP
2. Associating Track with a tracked list
   - Associating Track with a Boolean list
   - Associating Track with a percentage threshold list
   - Associating Track with a weight threshold list
3. Associating the Track module with an application module
   - Associating Track with VRRP
   - Associating Track with static routing
   - Associating Track with PBR
   - Associating Track with Smart Link
   - Associating Track with EAA
   - Associating Track with ERPS

Associating the Track module with a detection module

Associating Track with NQA

About this task

NQA supports multiple operation types to analyze network performance and service quality. For example, an NQA operation can periodically detect whether a destination is reachable, or whether a TCP connection can be established.

An NQA operation operates as follows when it is associated with a track entry:

- If the consecutive probe failures reach the specified threshold, the NQA module notifies the Track module that the tracked object has malfunctioned. The Track module then sets the track entry to Negative state.
- If the specified threshold is not reached, the NQA module notifies the Track module that the tracked object is operating correctly. The Track module then sets the track entry to Positive state.

For more information about NQA, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

If you associate a track entry with a nonexistent NQA operation or reaction entry, the state of the track entry is NotReady.

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with an NQA reaction entry, and enter its view.

   track *track-entry-number* **nqa entry** *admin-name operation-tag* **reaction** *item-number*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with BFD

About this task

You can associate a track entry with an echo-mode BFD session, a control-mode BFD session, or a static BFD session. For more information about BFD, see "Configuring BFD."

The associated Track and BFD operate as follows:

- If the BFD detects that the link fails, it informs the Track module of the link failure. The Track module sets the track entry to Negative state.
- If the BFD detects that the link is operating correctly, the Track module sets the track entry to Positive state.

Restrictions and guidelines

When you associate a track entry with BFD, do not configure the virtual IP address of a VRRP group as the local or remote address of the BFD session.

For correct establishment of a control-mode BFD session, follow these guidelines when you execute the **track bfd ctrl** command:

- Execute the **track bfd ctrl** command on both the local and peer ends.
- Specify the BFD session parameters (outgoing interface, source IP address, and destination IP address of BFD control packets) correctly for the command.

Prerequisites

Before you associate Track with an echo-mode BFD session, configure the source IP address of BFD echo packets. For more information, see "Configuring BFD."

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with a BFD session, and enter its view. Choose the options to configure as needed:
   - Create a track entry, and associate it with an echo-mode BFD session.

     track *track-entry-number* **bfd echo interface** *interface-type interface-number* **remote** { **ip** *remote-ip-address* | **ipv6** *remote-ipv6-address* } **local** { **ip** *local-ip-address* | **ipv6** *local-ipv6-address* }
   - Create a track entry, and associate it with a control-mode BFD session.

     track *track-entry-number* **bfd ctrl** [**interface** *interface-type interface-number* | **vpn-instance** *vpn-instance-name*] **remote** { **ip** *remote-ip-address* | **ipv6** *remote-ipv6-address* } **local** { **ip** *local-ip-address* | **ipv6** *local-ipv6-address* }
   - Create a track entry, and associate it with a static BFD session.

     track *track-entry-number* **bfd static** *bfd-session-name*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with CFD

About this task

The associated Track and CFD operate as follows:

- If the CFD detects that the link fails, it informs the Track module of the link failure. The Track module then sets the track entry to Negative state.
- If the CFD detects that the link is operating correctly, the Track module sets the track entry to Positive state.

For more information about CFD, see "Configuring CFD."

Prerequisites

Before you associate Track with CFD, enable CFD and create a MEP. For more information, see "Configuring CFD."

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with CFD, and enter its view.

track *track-entry-number* **cfd cc service-instance** *instance-id* **mep** *mep-id*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with interface management

About this task

The interface management module monitors the link status or network-layer protocol status of interfaces. The associated Track and interface management operate as follows:

- When the link or network-layer protocol status of the interface changes to up, the interface management module informs the Track module of the change. The Track module sets the track entry to Positive state.
- When the link or network-layer protocol status of the interface changes to down, the interface management module informs the Track module of the change. The Track module sets the track entry to Negative state.

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with interface management, and enter its view.
   - Create a track entry to monitor the link status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number*
   - Create a track entry to monitor the physical status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number* **physical**
   - Create a track entry to monitor the network layer protocol status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number* **protocol** { **ipv4** | **ipv6** }
3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with route management

About this task

The route management module monitors route entry changes in the routing table. The associated Track and route management operate as follows:

- When a monitored route entry is found in the routing table, the route management module informs the Track module. The Track module sets the track entry to Positive state.
- When a monitored route entry is removed from the routing table, the route management module informs the Track module of the change. The Track module sets the track entry to Negative state.

Procedure

1. Enter system view.
   system-view
2. Create a track entry, associate it with a route entry, and enter its view.
   track *track-entry-number* **ip route** [**vpn-instance** *vpn-instance-name*] **ip-address** { *mask-length* | *mask* } **reachability**
3. Set the delay for notifying the application module of track entry state changes.
   delay { **negative** *negative-time* | **positive** *positive-time* } *
   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with LLDP

About this task

The LLDP module detects neighbor availability and informs the detection result to the Track module. The associated Track and LLDP operate as follows:

- When the neighbor is available, the Track module sets the track entry to Positive state.
- When the neighbor is unavailable, the Track module sets the track entry to Negative state.

For more information about LLDP, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Create a track entry, associate it with an LLDP interface, and enter its view.
   track *track-entry-number* **lldp neighbor interface** *interface-type interface-number*
3. Set the delay for notifying the application module of track entry state changes.
   delay { **negative** *negative-time* | **positive** *positive-time* } *
   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with a tracked list

Associating Track with a Boolean list

About this task

A Boolean list is a list of tracked objects based on a Boolean logic. It can be further divided into the following types:

- **Boolean AND list**—A Boolean AND list is set to the Positive state only when all objects are in Positive state. If one or more objects are in Negative state, the tracked list is set to the Negative state.
- **Boolean OR list**—A Boolean OR list is set to the Positive state if any object is in Positive state. If all objects are in Negative state, the tracked list is set to the Negative state.

Procedure

1. Enter system view.
   system-view

2. Create a Boolean tracked list and enter its view.

   track *track-entry-number* **list boolean** { **and** | **or** }

3. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.

4. Add the track entry as an object to the tracked list.

   object *track-entry-number* [**not**]

   By default, a tracked list does not contain any objects.

   Repeat this step to add all interested objects to the tracked list.

Associating Track with a percentage threshold list

About this task

The state of a percentage threshold list is determined by comparing the percentage of positive objects in the list with the percentage thresholds configured for the list.

- If the percentage of positive objects is equal to or above the positive state threshold, the list is set to the Positive state.
- If the percentage of positive objects is equal to or below the negative state threshold, the list is set to the Negative state.
- The state of a percentage threshold list remains unchanged if the percentage of positive objects is below the positive state threshold and above the negative state threshold.

Procedure

1. Enter system view.

   system-view

2. Create a percentage threshold list and enter its view.

   track *track-entry-number* **list threshold percentage**

3. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.

4. Add the track entry as an object to the tracked list.

   object *track-entry-number*

   By default, a tracked list does not contain any objects.

   Repeat this step to add all interested objects to the tracked list.

5. Configure the threshold values used to determine the state of the percentage threshold list.

   threshold percentage { **negative** *negative-threshold* | **positive** *positive-threshold* } *

   By default, the negative state threshold is 0% and the positive state threshold is 1%.

Associating Track with a weight threshold list

About this task

The state of a weight threshold list is determined by comparing the weight of positive objects in the list with the weight thresholds configured for the list.

- If the total weight of positive objects is equal to or above the positive state threshold, the list is set to the Positive state.
- If the total weight of positive objects is equal to or below the negative state threshold, the list is set to the Negative state.
- The state of a weight threshold list remains unchanged if the total weight of positive objects is below the positive state threshold and above the negative state threshold.

Procedure

1. Enter system view.
   system-view
2. Create a weight threshold list and enter its view.
   track *track-entry-number* **list threshold weight**
3. (Optional.) Set the delay for notifying the application module of tracked list state changes.
   delay { **negative** *negative-time* | **positive** *positive-time* } *
   By default, the Track module notifies the application module immediately when the tracked list state changes.
4. Add the track entry as an object to the tracked list.
   object *track-entry-number* [**weight** *weight*]
   By default, a tracked list does not contain any objects.
   Repeat this step to add all interested objects to the tracked list.
5. Configure the threshold values used to determine the state of the weight threshold list.
   threshold weight { **negative** *negative-threshold* | **positive** *positive-threshold* } *
   By default, the negative state threshold is 0 and the positive state threshold is 1.

Associating the Track module with an application module

Before you associate the Track module with an application module, make sure the associated track entry has been created.

Prerequisites for associating the Track module with an application module

Create a track entry first before you associate it with an application module.

An application module might obtain incorrect track entry status information if the associated track entry does not exist.

Associating Track with VRRP

About this task

When VRRP is operating in standard mode or load balancing mode, associate the Track module with the VRRP group to implement the following actions:

- Change the priority of a router according to the status of the uplink. If a fault occurs on the uplink of the router, the VRRP group is not aware of the uplink failure. If the router is the master, hosts in the LAN cannot access the external network. To resolve this problem, configure a detection

module-Track-VRRP collaboration. The detection module monitors the status of the uplink of the router and notifies the Track module of the detection result.

When the uplink fails, the detection module notifies the Track module to change the status of the monitored track entry to Negative. The priority of the master decreases by a user-specified value. A router with a higher priority in the VRRP group becomes the master.

- Monitor the master on a backup. If a fault occurs on the master, the backup operating in switchover mode will switch to the master immediately to maintain normal communication.

When VRRP is operating in load balancing mode, associate the Track module with the VRRP VF to implement the following functions:

- Change the priority of the AVF according to its uplink state. When the uplink of the AVF fails, the track entry changes to Negative state. The weight of the AVF decreases by a user-specified value. The VF with a higher priority becomes the new AVF to forward packets.
- Monitor the AVF status from the LVF. When the AVF fails, the LVF that is operating in switchover mode becomes the new AVF to ensure continuous forwarding.

For more information about configuring VRRP, see "Configuring VRRP."

Restrictions and guidelines for Track association with VRRP

- VRRP tracking does not take effect on an IP address owner. The configuration takes effect when the router does not act as the IP address owner.

  An IP address owner is the router with its interface IP address used as the virtual IP address of the VRRP group.
- When the status of the track entry changes from Negative to Positive or NotReady, the associated router or VF restores its priority automatically.

Associating Track with a VRRP group

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Associate a track entry with a VRRP group.

   vrrp [**ipv6**] **vrid** *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] **switchover** | **weight reduced** [*weight-reduced*] }

   By default, no track entry is associated with a VRRP group.

   This command is supported when VRRP is operating in both standard mode and load balancing mode.

Associating Track with a VRRP VF

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Associate Track with a VRRP VF.

   vrrp [**ipv6**] **vrid** *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] **switchover** | **weight reduced** [*weight-reduced*] }

   By default, no track entry is associated with a VRRP VF.

   This command is configurable when VRRP is operating in standard mode or load balancing mode. However, the configuration takes effect only when VRRP is operating in load balancing mode.

Associating Track with static routing

About this task

A static route is a manually configured route to route packets. For more information about static route configuration, see *Layer 3—IP Routing Configuration Guide*.

Static routes cannot adapt to network topology changes. Link failures or network topological changes can make the routes unreachable and cause communication interruption.

To resolve this problem, configure another route to back up the static route. When the static route is reachable, packets are forwarded through the static route. When the static route is unreachable, packets are forwarded through the backup route.

To check the accessibility of a static route in real time, associate the Track module with the static route.

If you specify the next hop but not the output interface when configuring a static route, you can configure the static routing-Track-detection module collaboration. This collaboration enables you to verify the accessibility of the static route based on the track entry state.

- If the track entry is in Positive state, the following conditions exist:
  - The next hop of the static route is reachable.
  - The configured static route is valid.
- If the track entry is in Negative state, the following conditions exist:
  - The next hop of the static route is not reachable.
  - The configured static route is invalid.
- If the track entry is in NotReady state, the following conditions exist:
  - The accessibility of the next hop of the static route is unknown.
  - The static route is valid.

Restrictions and guidelines

In static routing-Track-NQA collaboration, you must configure the same VPN instance name for the NQA operation and the next hop of the static route. Otherwise, the accessibility detection cannot operate correctly.

If a static route needs route recursion, the associated track entry must monitor the next hop of the recursive route. The next hop of the static route cannot be monitored. Otherwise, a valid route might be considered invalid.

Associating Track with an IPv4 static route

1. Enter system view.

   system-view

2. Associate an IPv4 static route with a track entry to check the accessibility of the next hop.

   Public network:

   ip route-static { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* | **vpn-instance** *d-vpn-instance-name next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name* { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* |

next-hop-address [**recursive-lookup host-route**] [**public**] **track** *track-entry-number* | **vpn-instance** *d-vpn-instance-name* *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

By default, an IPv4 static route is not associated with any track entries.

Associating Track with an IPv6 static route

1. Enter system view.

   system-view

2. Associate an IPv6 static route with a track entry to check the accessibility of the next hop.

   Public network:

   ipv6 route-static *ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | [**vpn-instance** *d-vpn-instance-name*] *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ipv6 route-static vpn-instance *s-vpn-instance-name ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | *next-hop-address* [**public**] **track** *track-entry-number* | **vpn-instance** *d-vpn-instance-name* *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, an IPv6 static route is not associated with any track entries.

Associating Track with PBR

About this task

PBR uses user-defined policies to route packets. You can specify parameters in a PBR policy to guide the forwarding of the packets that match specific criteria. For more information about PBR, see *Layer 3—IP Routing Configuration Guide*.

PBR cannot detect the availability of any action taken on packets. When an action is not available, packets processed by the action might be discarded. For example, if the output interface specified for PBR fails, PBR cannot detect the failure, and continues to forward matching packets out of the interface.

To enable PBR to detect topology changes and improve the flexibility of the PBR application, configure Track-PBR-detection module collaboration.

After you associate a track entry with an apply clause, the detection module associated with the track entry sends Track the detection result of the availability of the tracked object.

- The Positive state of the track entry indicates that the object is available, and the apply clause is valid.
- The Negative state of the track entry indicates that the object is not available, and the apply clause is invalid.
- The NotReady state of the track entry indicates that the apply clause is valid.

The following objects can be associated with a track entry:

- Output interface.
- Next hop.

Prerequisites for Track association with PBR

Before you associate Track with PBR, create a policy node, and set the match criteria.

Associating Track with PBR

1. Enter system view.

   system-view

2. Create a policy node and enter its view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Set match criteria. Choose the options to configure as needed:

   - Set an ACL match criterion.

     if-match acl { *acl-number* | **name** *acl-name* }

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

     When using the ACL to match packets, PBR ignores the action (**permit** or **deny**) and time range settings in the ACL.

4. Set actions and associate the policy node with a track entry. Choose the options to configure as needed:

   - Set the output interface.

     apply output-interface null 0 [**track** *track-entry-number*]

     By default, no output interface is set.

   - Set the next hop.

     apply next-hop [**vpn-instance** *vpn-instance-name*] { *ip-address* [**direct**] [**track** *track-entry-number*] }&<1-6>

     By default, no next hop is set.

Associating Track with IPv6 PBR

1. Enter system view.

   system-view

2. Create an IPv6 policy node and enter its view.

   ipv6 policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Set match criteria. Choose the options to configure as needed:

   - Set an ACL match criterion.

     if-match acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

     When using the ACL to match packets, IPv6 PBR ignores the action (**permit** or **deny**) and time range settings in the ACL.

4. Set actions and associate the policy node with a track entry. Choose the options to configure as needed:

   - Set the output interface.

     apply output-interface null 0 [**track** *track-entry-number*]

     By default, no output interface is set.

   - Set the next hop.

     apply next-hop [**vpn-instance** *vpn-instance-name*] { *ipv6-address* [**direct**] [**track** *track-entry-number*] }&<1-6>

     By default, no next hop is set.

Associating Track with Smart Link

About this task

Smart Link cannot detect unidirectional links, misconnected fibers, or packet loss on intermediate devices or network paths of the uplink. It also cannot detect when faults are cleared. To check the link status, Smart Link ports must use link detection protocols. When a fault is detected or cleared, the link detection protocols inform Smart Link to switch over the links.

You can configure the collaboration between Smart Link and Track on a smart link group member port. Smart Link collaborates with the CC feature of CFD through the track entry to detect the link status on the port.

- When the track entry is in Positive state, the link is in normal state. Smart Link does not perform link switchover for the smart link group.
- When the track entry is in Negative state, the link has failed. Smart Link determines whether to perform link switchover according to the link preemption mode and port role configured in the smart link group.
- When the track entry is in NotReady state, the port state does not change.

For more information about Smart Link, see "Configuring Smart Link."

Restrictions and guidelines

The track entry to be used for collaboration with Smart Link must have been associated with the CC feature of CFD.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*
3. Configure collaboration between Smart Link and Track on the port.

   port smart-link group *group-id* **track** *track-entry-number*

   By default, the collaboration between Smart Link and Track is not configured.

Associating Track with EAA

About this task

You can configure EAA track event monitor policies to monitor the positive-to-negative or negative-to-positive state changes of track entries.

- If you specify only one track entry for a policy, EAA triggers the policy when it detects the specified state change on the track entry.
- If you specify multiple track entries for a policy, EAA triggers the policy when it detects the specified state change on the last monitored track entry. For example, if you configure a policy to monitor the positive-to-negative state change of multiple track entries, EAA triggers the policy when the last positive track entry monitored by the policy is changed to the Negative state.

You can set a suppression time for a track event monitor policy. The timer starts when the policy is triggered. The system does not process messages that report the monitored track event until the timer times out.

For more information about EAA, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Create a CLI-defined monitor policy and enter its view, or enter the view of an existing CLI-defined monitor policy.

   rtm cli-policy *policy-name*

3. Configure a track event.

   event track *track-entry-number-list* **state** { **negative** | **positive** } [**suppress-time** *suppress-time*]

   By default, a monitor policy does not monitor any track event.

Associating Track with ERPS

About this task

To detect and clear link faults typically for a fiber link, use ERPS with CFD and Track. You can associate ERPS ring member ports with the continuity check function of CFD through track entries. CFD reports link events only when the monitored VLAN is the control VLAN of the ERPS instance for the port.

Track changes the track entry state based on the monitoring result of CFD, and notifies the track entry state change to the associated EPRS ring.

- When the track entry is in Positive state, the link of the monitored ERPS ring member port is in normal state. The ERPS ring does not switch traffic to other links.
- When the track entry is in Negative state, the link of the monitored ERPS ring member port is faulty. The ERPS ring switches traffic to other links.
- When the track entry is in NotReady state, the state of the ERPS ring member port does not change.

For more information about ERPS, see "Configuring ERPS."

Restrictions and guidelines

Before you associate a port with a track entry, make sure the port has joined an ERPS instance.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*

3. Associate an ERPS ring member port with a track entry.

   port erps ring *ring-id* **instance** *instance-id* **track** *track-entry-index*

   By default, an ERPS ring member port is not associated with any track entries.

Display and maintenance commands for Track

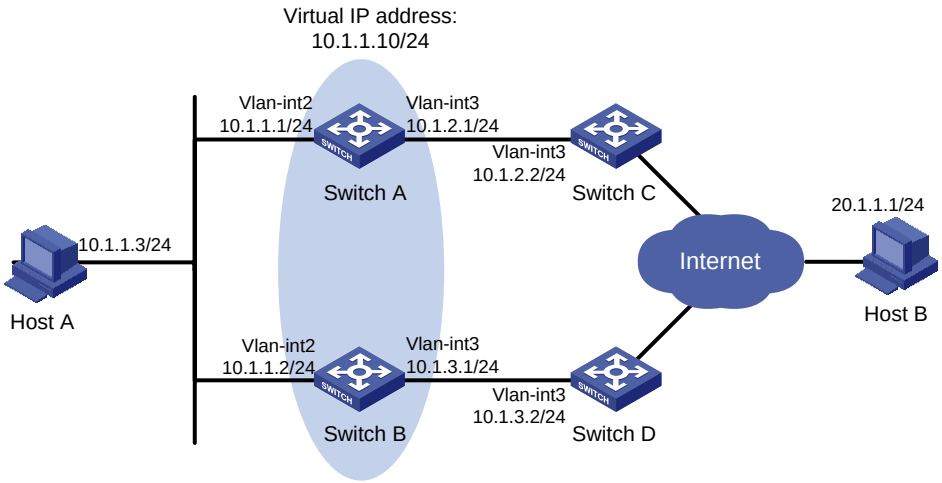
Execute **display** commands in any view.

Task	Command
Display information about track entries.	**display track** { *track-entry-number* | **all** [**negative** | **positive**] } [**brief**]

Track configuration examples

Example: Configuring VRRP-Track-NQA collaboration

Network configuration



As shown in Figure 2:

- Host A requires access to Host B. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 10.1.1.10.

Configure VRRP-Track-NQA collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, Switch A forwards packets from Host A to Host B.
- When NQA detects a fault on the uplink of Switch A, Switch B forwards packets from Host A to Host B.

Figure 2 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 2. (Details not shown.)
2. Configure an NQA operation on Switch A:

   # Create an NQA operation with administrator name **admin** and operation tag **test**.

   ```
   <SwitchA> system-view
   [SwitchA] nqa entry admin test
   ```

   # Specify the **ICMP echo** operation type.

   ```
   [SwitchA-nqa-admin-test] type icmp-echo
   ```

   # Specify 10.1.2.2 as the destination address of ICMP echo requests.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] destination ip 10.1.2.2
   ```

   # Configure the ICMP echo operation to repeat every 100 milliseconds.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] frequency 100
   ```

   # Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

```
[SwitchA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchA-nqa-admin-test-icmp-echo] quit
```

Start the NQA operation.

```
[SwitchA] nqa schedule admin test start-time now lifetime forever
```

3. On Switch A, configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchA] track 1 nqa entry admin test reaction 1
[SwitchA-track-1] quit
```

4. Configure VRRP on Switch A:

Specify VRRPv2 to run on VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp version 2
```

Create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

Set the priority of Switch A to 110 in VRRP group 1.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

Set the authentication mode of VRRP group 1 to **simple**, and the authentication key to **hello**.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
```

Configure the master to send VRRP packets every 500 centiseconds.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 timer advertise 500
```

Configure Switch A to operate in preemptive mode and set the preemption delay to 5000 centiseconds.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5000
```

Associate VRRP group 1 with track entry 1 and decrease the router priority by 30 when the state of track entry 1 changes to Negative.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 30
```

5. Configure VRRP on Switch B:

Specify VRRPv2 to run on VLAN-interface 2.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp version 2
```

Create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

Set the authentication mode of VRRP group 1 to **simple**, and the authentication key to **hello**.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
```

Configure the master to send VRRP packets every 500 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 timer advertise 500
```

Configure Switch B to operate in preemptive mode and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5000
```

Verifying the configuration

Ping Host B from Host A to verify that Host B is reachable. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose

```

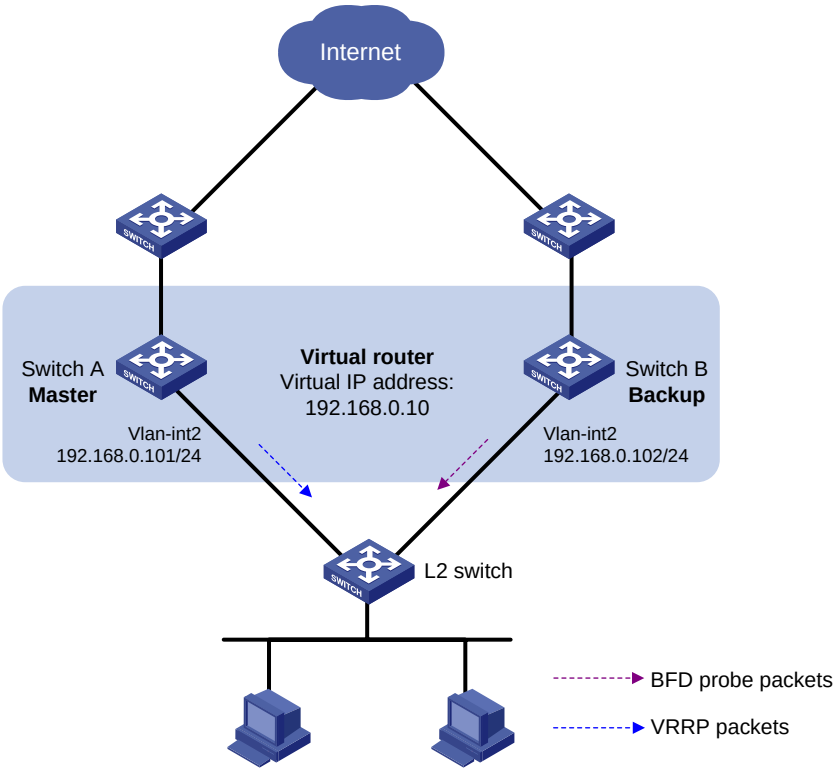
The output shows that Switch A becomes the backup, and Switch B becomes the master. Switch B forwards packets from Host A to Host B.

Example: Configuring an echo-mode BFD session for a VRRP backup to monitor the master

Network configuration



As shown in Figure 3:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (echo mode) collaboration to monitor the master on the backup and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A fails, the backup (Switch B) can detect the state change of the master through the echo-mode BFD session and become the new master. The hosts in the LAN access the Internet through Switch B.

Figure 3 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 3. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   [SwitchA-Vlan-interface2] return
   ```

3. Configure Switch B:

   # Specify 10.10.10.10 as the source address of BFD echo packets.

   ```
   <SwitchB> system-view
   [SwitchB] bfd echo-source-ip 10.10.10.10
   ```

   # Create track entry 1, and associate it with the echo-mode BFD session to verify the reachability of Switch A.

   ```
   [SwitchB] track 1 bfd echo interface vlan-interface 2 remote ip 192.168.0.101 local
   ip 192.168.0.102
   [SwitchB-track-1] quit
   ```

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Configure VRRP group 1 to monitor the status of track entry 1.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 track 1 switchover
[SwitchB-Vlan-interface2] return
```

Verifying the configuration

*Dec 17 14:44:34:144 2019 SwitchB VRRP4/7/FSM:
 IPv4 Vlan-interface2 | Virtual Router 1 : Backup --> Master   reason: The status of the
tracked object changed
```

Display detailed information about the VRRP group on Switch B.

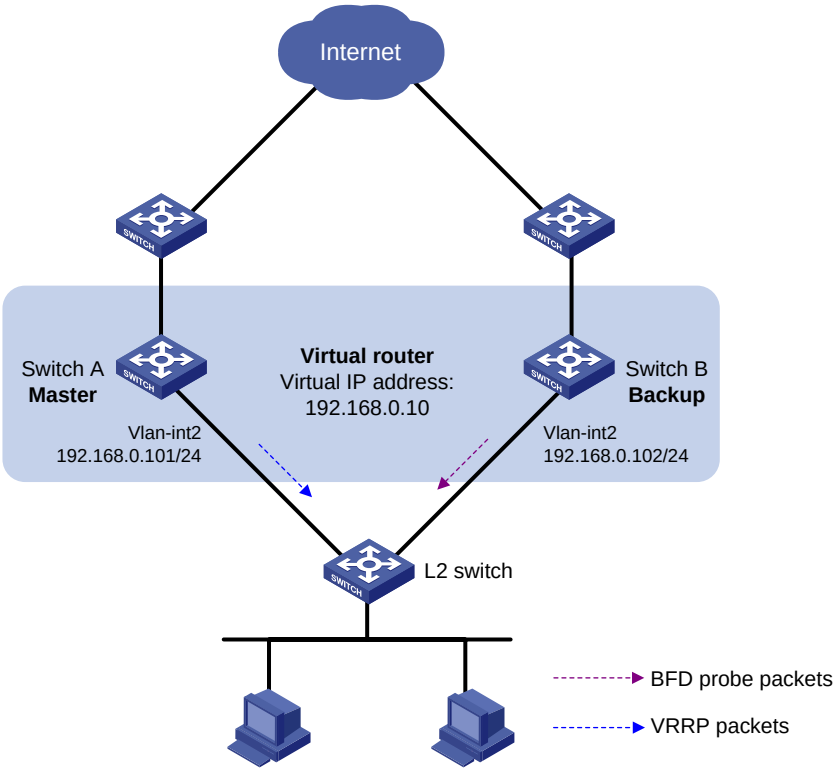
```
<SwitchB> display vrrp verbose
IPv4 Virtual Router Information:
 Running Mode      : Standard
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1                Adver Timer   : 100
     Admin Status     : Up               State         : Master
     Config Pri       : 100              Running Pri   : 100
     Preempt Mode     : Yes              Delay Time    : 0
     Auth Type        : Not supported
     Version          : 3
     Virtual IP       : 192.168.0.10
     Virtual MAC      : 0000-5e00-0101
     Master IP        : 192.168.0.102
   VRRP Track Information:
     Track Object   : 1              State : Negative          Switchover
```

The output shows that when the echo-mode BFD session detects that Switch A fails, the Track module notifies VRRP to change the status of Switch B to master. The backup can quickly preempt as the master without waiting for a period three times the advertisement interval plus the Skew_Time.

Example: Configuring a control-mode BFD session for a VRRP backup to monitor the master

Network configuration

As shown in Figure 4:



- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (control mode) collaboration to monitor the master on the backup and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.

- When Switch A fails, the backup (Switch B) can detect the state change of the master through the control-mode BFD session and become the new master. The hosts in the LAN access the Internet through Switch B.

Figure 4 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 4. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   [SwitchA-Vlan-interface2] return
   ```

   # Create track entry 1, and associate it with the control-mode BFD session to verify the reachability of Switch B.

   ```
   [SwitchA] track 1 bfd ctrl interface vlan-interface 2 remote ip 192.168.0.102 local
   ip 192.168.0.101
   [SwitchA-track-1] quit
   ```
3. Configure Switch B:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

Configure VRRP group 1 to monitor track entry 1 so Switch B can take over as the master once the track entry changes to the Negative state.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 track 1 switchover
[SwitchB-Vlan-interface2] return
```

Create track entry 1, and associate it with the control-mode BFD session to verify the reachability of Switch A.

```
[SwitchB] track 1 bfd ctrl interface vlan-interface 2 remote ip 192.168.0.101 local
ip 192.168.0.102
[SwitchB-track-1] quit
```

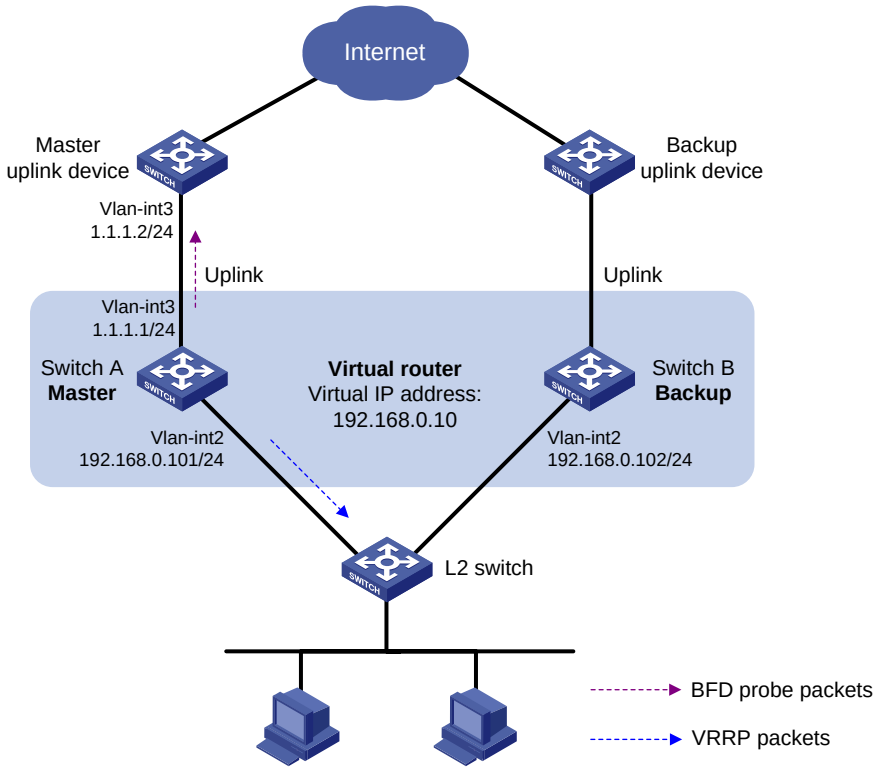
The output shows that when the control-mode BFD session detects that Switch A fails, the Track module notifies VRRP to change the status of Switch B to master. The backup can quickly preempt as the master without waiting for a period three times the advertisement interval plus the Skew_Time.

Example: Configuring an echo-mode BFD session for the VRRP master to monitor the uplink

Network configuration



As shown in Figure 5:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (echo mode) collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A detects that the uplink is down through the echo-mode BFD session, Switch B can preempt as the master. The hosts in the LAN can access the Internet through Switch B.

Figure 5 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 5. (Details not shown.)
2. Configure Switch A:

   # Specify 10.10.10.10 as the source address of BFD echo packets.

   ```
   <SwitchA> system-view
   [SwitchA] bfd echo-source-ip 10.10.10.10
   ```

   # Create track entry 1 for the echo-mode BFD session to verify the reachability of the uplink device (1.1.1.2).

   ```
   [SwitchA] track 1 bfd echo interface vlan-interface 3 remote ip 1.1.1.2 local ip
   1.1.1.1
   [SwitchA-track-1] quit
   ```

   # Create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

Associate VRRP group 1 with track entry 1 and decrease the router priority by 20 when the state of track entry 1 changes to Negative.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 20
[SwitchA-Vlan-interface2] return
```

3. On Switch B, create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
[SwitchB-Vlan-interface2] return
```

Verifying the configuration

Display detailed information about the VRRP group on Switch A.

Virtual MAC      : 0000-5e00-0101
Master IP        : 192.168.0.102
```

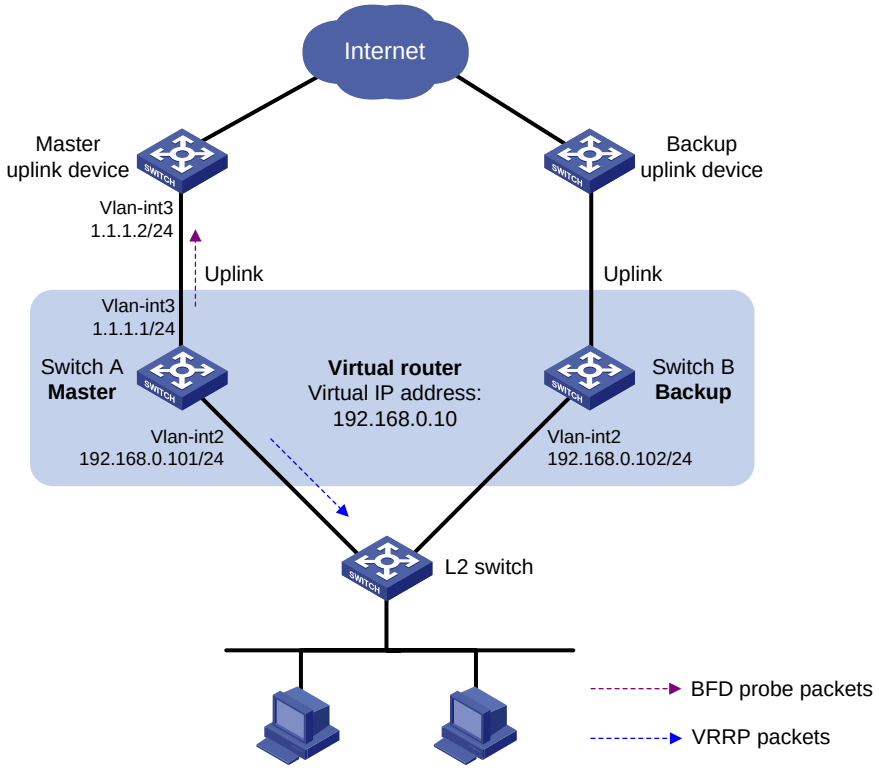
The output shows that when Switch A detects that the uplink fails through the echo-mode BFD session, it decreases its priority by 20. Switch B then preempts as the master.

Example: Configuring a control-mode BFD session for the VRRP master to monitor the uplink

Network configuration



As shown in Figure 6:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (control mode) collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A detects that the uplink is down through the control-mode BFD session, Switch B can preempt as the master. The hosts in the LAN can access the Internet through Switch B.

Figure 6 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 6. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

   # Associate VRRP group 1 with track entry 1 and decrease the router priority by 20 when the state of track entry 1 changes to Negative.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 20
   [SwitchA-Vlan-interface2] quit
   ```

   # Create track entry 1 for the control-mode BFD session to monitor the reachability of the uplink device (1.1.1.2).

   ```
   [SwitchA] track 1 bfd ctrl interface vlan-interface 3 remote ip 1.1.1.2 local ip
   1.1.1.1
   [SwitchA-track-1] quit
   ```

3. On the uplink device of Switch A, create track entry 1 and associate it with the control-mode BFD session to verify the reachability of the Switch A.

   ```
   <Master> system-view
   [Master] track 1 bfd ctrl interface vlan-interface 3 remote ip 1.1.1.1 local ip 1.1.1.2
   ```

4. On Switch B, create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   [SwitchB-Vlan-interface2] return
   ```

Verifying the configuration

```

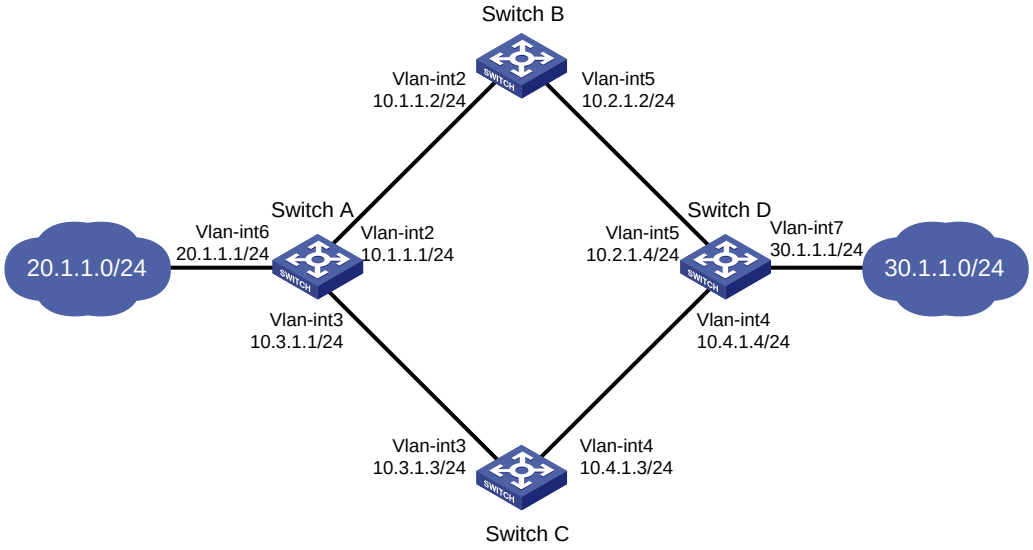
The output shows that when Switch A detects that the uplink fails through the control-mode BFD session, it decreases its priority by 20. Switch B then preempts as the master.

Example: Configuring static routing-Track-NQA collaboration

Network configuration



As shown in Figure 7:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch D is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-NQA collaboration on Switch A and Switch D as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the backup route takes effect. Switch A forwards packets to 30.1.1.0/24 through Switch C.
- On Switch D, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the backup route takes effect. Switch D forwards packets to 20.1.1.0/24 through Switch C.

Figure 7 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 7. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.1.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.1.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Configure a static route to 10.2.1.4 with next hop 10.1.1.2.

   ```
   [SwitchA] ip route-static 10.2.1.4 24 10.1.1.2
   ```

   # Create an NQA operation with administrator name **admin** and operation tag **test**.

   ```
   [SwitchA] nqa entry admin test
   ```

   # Specify the **ICMP echo** operation type.

   ```
   [SwitchA-nqa-admin-test] type icmp-echo
   ```

   # Specify 10.2.1.4 as the destination address of the operation.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] destination ip 10.2.1.4
   ```

   # Specify 10.1.1.2 as the next hop of the operation.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] next-hop ip 10.1.1.2
   ```

   # Configure the ICMP echo operation to repeat every 100 milliseconds.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] frequency 100
   ```

   # Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
   threshold-type consecutive 5 action-type trigger-only
   [SwitchA-nqa-admin-test-icmp-echo] quit
   ```

   # Start the NQA operation.

   ```
   [SwitchA] nqa schedule admin test start-time now lifetime forever
   ```

   # Configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchA] track 1 nqa entry admin test reaction 1
[SwitchA-track-1] quit
```

3. Configure Switch B:

Configure a static route to 30.1.1.0/24 with next hop 10.2.1.4.

```
<SwitchB> system-view
[SwitchB] ip route-static 30.1.1.0 24 10.2.1.4
```

Configure a static route to 20.1.1.0/24 with next hop 10.1.1.1.

```
[SwitchB] ip route-static 20.1.1.0 24 10.1.1.1
```

4. Configure Switch C:

Configure a static route to 30.1.1.0/24 with next hop 10.4.1.4.

```
<SwitchC> system-view
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.4
```

Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
```

5. Configure Switch D:

Configure a static route to 20.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

```
<SwitchD> system-view
[SwitchD] ip route-static 20.1.1.0 24 10.2.1.2 track 1
```

Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

```
[SwitchD] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
```

Configure a static route to 10.1.1.1 with next hop 10.2.1.2.

```
[SwitchD] ip route-static 10.1.1.1 24 10.2.1.2
```

Create an NQA operation with administrator name **admin** and operation tag **test**.

```
[SwitchD] nqa entry admin test
```

Specify the **ICMP echo** operation type.

```
[SwitchD-nqa-admin-test] type icmp-echo
```

Specify 10.1.1.1 as the destination address of the operation.

```
[SwitchD-nqa-admin-test-icmp-echo] destination ip 10.1.1.1
```

Specify 10.2.1.2 as the next hop of the operation.

```
[SwitchD-nqa-admin-test-icmp-echo] next-hop ip 10.2.1.2
```

Configure the ICMP echo operation to repeat every 100 milliseconds.

```
[SwitchD-nqa-admin-test-icmp-echo] frequency 100
```

Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

```
[SwitchD-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchD-nqa-admin-test-icmp-echo] quit
```

Start the NQA operation.

```
[SwitchD] nqa schedule admin test start-time now lifetime forever
```

Configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchD] track 1 nqa entry admin test reaction 1
[SwitchD-track-1] quit
```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
```

```
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: NQA
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test
    Reaction: 1
    Remote IP/URL: 10.2.1.4
    Local IP:--
    Interface:--
```

The output shows that the status of the track entry is Positive, indicating that the NQA operation has succeeded and the master route is available.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 10       Routes : 10

20.1.1.0/24         Direct 0    0            20.1.1.1        Vlan6
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.1.1.2        Vlan2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch B.

Remove the IP address of interface VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: NQA
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test
    Reaction: 1
    Remote IP/URL: 10.2.1.4
    Local IP:--
    Interface:--
```

The output shows that the status of the track entry is Negative, indicating that the NQA operation has failed and the master route is unavailable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 10       Routes : 10

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.1.1.0/24         Direct 0    0            10.1.1.1        Vlan2
10.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.2.1.0/24         Static 60   0            10.1.1.2        Vlan2

round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

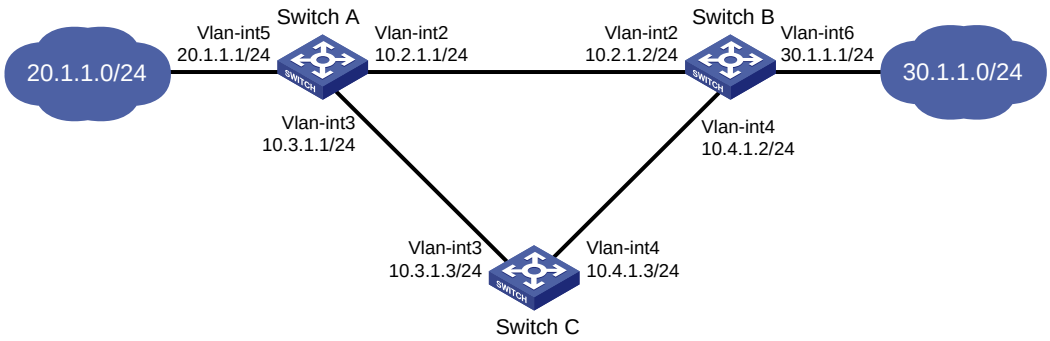
Example: Configuring static routing-Track-BFD (echo mode) collaboration

Network configuration



As shown in Figure 8:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-BFD (echo mode) collaboration on Switch A and Switch B as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the echo-mode BFD session can quickly detect the route failure to make the backup route take effect.
- On Switch B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch A. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the echo-mode BFD session can quickly detect the route failure to make the backup route take effect.

Figure 8 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 8. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Specify 10.10.10.10 as the source address of BFD echo packets.

   ```
   [SwitchA] bfd echo-source-ip 10.10.10.10
   ```

   # Configure track entry 1, and associate it with the echo-mode BFD session to verify the connectivity between Switch A and Switch B.

   ```
   [SwitchA] track 1 bfd echo interface vlan-interface 2 remote ip 10.2.1.2 local ip
   10.2.1.1
   [SwitchA-track-1] quit
   ```

3. Configure Switch B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

```
<SwitchB> system-view
[SwitchB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

```
[SwitchB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
```

   # Specify 1.1.1.1 as the source address of BFD echo packets.

```
[SwitchB] bfd echo-source-ip 1.1.1.1
```

   # Configure track entry 1, and associate it with the echo-mode BFD session to verify the connectivity between Switch B and Switch A.

```
[SwitchB] track 1 bfd echo interface vlan-interface 2 remote ip 10.2.1.1 local ip
10.2.1.2
[SwitchB-track-1] quit
```

4. Configure Switch C:

   # Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

```
<SwitchC> system-view
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.2
```

   # Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD echo
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Echo
    Outgoing interface: Vlan-interface2
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Positive, indicating that next hop 10.2.1.2 is reachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        Vlan2
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        Vlan3
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        Vlan5
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
```

```
30.1.1.0/24         Static 60   0            10.2.1.2        Vlan2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch B. The master static route has taken effect.

Remove the IP address of VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD echo
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Echo
    Outgoing interface: Vlan-interface2
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Negative, indicating that next hop 10.2.1.2 is unreachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

```

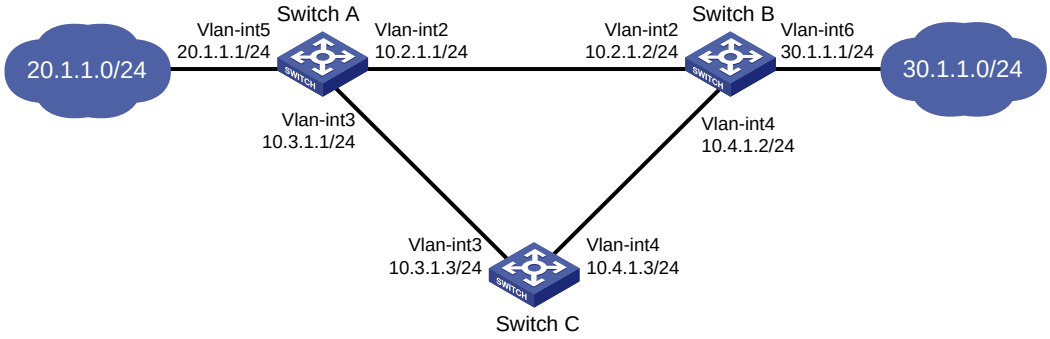
Example: Configuring static routing-Track-BFD (control mode) collaboration

Network configuration



As shown in Figure 9:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-BFD (control mode) collaboration on Switch A and Switch B as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the control-mode BFD session can quickly detect the route failure to make the backup route take effect.
- On Switch B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch A. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the control-mode BFD session can quickly detect the route failure to make the backup route take effect.

Figure 9 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 9. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Configure track entry 1, and associate it with the control-mode BFD session to verify the connectivity between Switch A and Switch B.

   ```
   [SwitchA] track 1 bfd ctrl interface vlan-interface 2 remote ip 10.2.1.2 local ip 10.2.1.1
   [SwitchA-track-1] quit
   ```

3. Configure Switch B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchB> system-view
   [SwitchB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

   ```
   [SwitchB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
   ```

   # Configure track entry 1, and associate it with the control-mode BFD session to verify the connectivity between Switch B and Switch A.

   ```
   [SwitchB] track 1 bfd ctrl interface vlan-interface 2 remote ip 10.2.1.1 local ip 10.2.1.2
   [SwitchB-track-1] quit
   ```

4. Configure Switch C:

   # Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

   ```
   <SwitchC> system-view
   [SwitchC] ip route-static 30.1.1.0 24 10.4.1.2
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

   ```
   [SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
   ```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
```

```
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD ctrl
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Ctrl
    Outgoing interface: Vlan-interface2
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Positive, indicating that next hop 10.2.1.2 is reachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        Vlan2
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        Vlan3
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        Vlan5
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.2.1.2        Vlan2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch B. The master static route has taken effect.

Remove the IP address of VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD ctrl
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Ctrl
    Outgoing interface: Vlan-interface2
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Negative, indicating that next hop 10.2.1.2 is unreachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        Vlan5
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 80   0            10.3.1.3        Vlan3
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch C. The backup static route has taken effect.

Verify that the hosts in 20.1.1.0/24 can communicate with the hosts in 30.1.1.0/24 when the master route fails.

```
[SwitchA] ping -a 20.1.1.1 30.1.1.1
Ping 30.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 30.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
Reply from 30.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms
Reply from 30.1.1.1: bytes=56 Sequence=4 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 30.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Verify that the hosts in 30.1.1.0/24 can still communicate with the hosts in 20.1.1.0/24 when the master route fails.

```
[SwitchB] ping -a 30.1.1.1 20.1.1.1
Ping 20.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 20.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 20.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
Reply from 20.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms

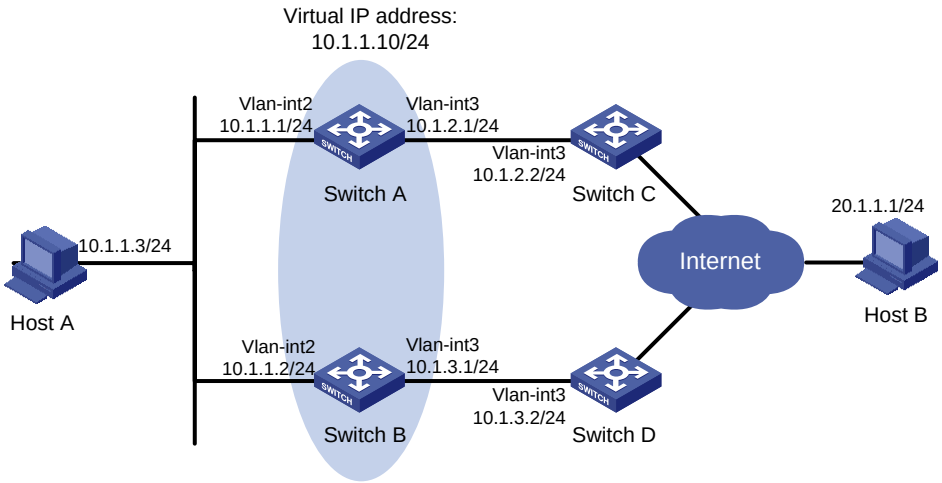
Reply from 20.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 20.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Example: Configuring VRRP-Track-interface management collaboration

Network configuration



As shown in Figure 10:

- Host A requires access to Host B. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 10.1.1.10.

Configure VRRP-Track-interface management collaboration to monitor the uplink interface on the master and meet the following requirements:

- When Switch A operates correctly, Switch A forwards packets from Host A to Host B.
- When VRRP detects a fault on the uplink interface of Switch A through the interface management module, Switch B forwards packets from Host A to Host B.

Figure 10 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 10. (Details not shown.)
2. Configure Switch A:

   # Configure track entry 1 and associate it with the link status of the uplink interface VLAN-interface 3.

   ```
   [SwitchA] track 1 interface vlan-interface 3
   [SwitchA-track-1] quit
   ```

   # Create VRRP group 1 and configure virtual IP address 10.1.1.10 for the group.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

   # Associate VRRP group 1 with track entry 1 and decrease the router priority by 30 when the state of track entry 1 changes to Negative.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 30
   ```

3. On Switch B, create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

   ```
   <SwitchB> system-view
   ```

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

Verifying the configuration

Ping Host B from Host A to verify that Host B is reachable. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:

     Config Pri       : 100             Running Pri  : 100
     Preempt Mode     : Yes             Delay Time   : 0
     Auth Type        : Not supported
     Version          : 3
     Virtual IP       : 10.1.1.10
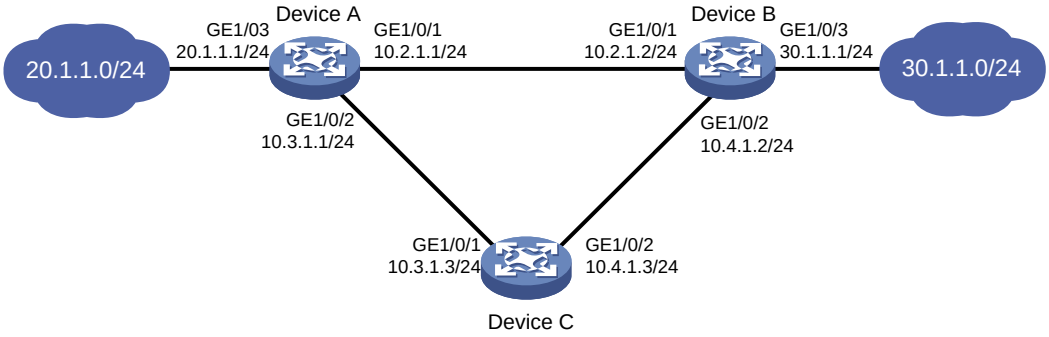
     Virtual MAC      : 0000-5e00-0101
     Master IP        : 10.1.1.2
```

The output shows that Switch A becomes the backup, and Switch B becomes the master. Switch B forwards packets from Host A to Host B.

Example: Configuring static routing-Track-LLDP collaboration

Network requirements



As shown in Figure 11:

- Device A is the default gateway of the hosts in network 20.1.1.0/24.
- Device B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-LLDP collaboration on Device A and Device B as follows:

- On Device A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Device B. This route is the master route. The static route to 30.1.1.0/24 with next hop Device C acts as the backup route. When the master route is unavailable, the backup route takes effect. Device A forwards packets destined for 30.1.1.0/24 to Device C.
- On Device B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Device A. This route is the master route. The static route to 20.1.1.0/24 with next hop Device C acts as the backup route. When the master route is unavailable, the backup route takes effect. Device B forwards packets destined for 20.1.1.0/24 to Device C.

Figure 11 Network diagram

Procedure

1. Configure the IP address of each interface, as shown in Figure 11. (Details not shown.)
2. Configure Device A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.1.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <DeviceA> system-view
   [DeviceA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [DeviceA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Enable LLDP globally.

   ```
   [DeviceA] lldp global enable
   ```

   # Enable LLDP on GigabitEthernet 1/0/1. (This step is optional because LLDP is enabled on the port by default.)

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] lldp enable
   ```

   # Configure track entry 1 and associate it with the availability of the neighbor for LLDP interface Gigabitethernet 1/0/1.

   ```
   [DeviceA] track 1 lldp neighbor interface gigabitethernet 1/0/1
   [DeviceA-track-1] quit
   ```

3. Configure Device B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

   ```
   <DeviceB> system-view
   [DeviceB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

   ```
   [DeviceB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
   ```

   # Enable LLDP globally.

   ```
   [DeviceB] lldp global enable
   ```

   # Enable LLDP on GigabitEthernet 1/0/1. (This step is optional because LLDP is enabled on the port by default.)

   ```
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] lldp enable
   ```

   # Configure track entry 1 and associate it with the availability of the neighbor for LLDP interface GigabitEthernet 1/0/1.

   ```
   [DeviceB] track 1 lldp neighbor interface gigabitethernet 1/0/1
   [DeviceB-track-1] quit
   ```

4. Configure Device C:

   # Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

```
<DeviceC> system-view
[DeviceC] ip route-static 30.1.1.0 24 10.4.1.2
```

   # Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[DeviceC] ip route-static 20.1.1.0 24 10.3.1.1
```

Verifying the configuration

Display track entry information on Device A.

```
[DeviceA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: LLDP
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    LLDP interface: GigabitEthernet1/0/1
```

The output shows that the status of track entry 1 is Positive, indicating that the neighbor of LLDP interface GigabitEthernet 1/0/1 is available. The master route takes effect.

Display the routing table of Device A.

```
[DeviceA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        GE1/0/1
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0

10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.2.1.2        GE1/0/1
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Device A forwards packets to 30.1.1.0/24 through Device B.

On Device B, disable LLDP on GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] undo lldp enable
```

Display track entry information on Device A.

```
[DeviceA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: LLDP
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    LLDP interface: GigabitEthernet1/0/1
```

The output shows that the status of track entry 1 is Negative, indicating that the neighbor of LLDP interface GigabitEthernet 1/0/1 is unavailable. The master route fails.

Display the routing table of Device A.

```
[DeviceA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface

Configuring process placement

About process placement

Process

A process contains a set of codes and provides specific functionality. For example, an AAA process provides AAA functions.

Each process runs in a protected memory space to prevent problems with one process from impacting the entire system.

Node

The term "node" in this document refers to CPUs that run the Comware system. If the IRF fabric has multiple member devices, each member device has a node.

Process redundancy

The system backs up each active process running on one node to all the other nodes. When an active process fails, one of its standby processes promptly takes over without impacting any other service.

Process redundancy provides the following benefits:

- Improves service availability.
- Enables the system to quickly regain reliability after device status changes in such conditions as insertion and removal of cards and removal of an IRF member.

Process placement

The execution of process placement policies varies by the location of active processes.

- An active process running only on the master device does not support placement optimization. If you configure a process placement policy for the process, the system displays a configuration failure message. When such an active process fails, the system automatically restarts the process. The standby processes are used for active/standby switchover.
- Some active processes can run on either the master or subordinate device. When such an active process fails, the system uses a placement policy to select a new active process among standby processes.

Default process placement policy

The system provides a default process placement policy that takes effect for all processes. By default, the default process placement policy defines the following rules:

- The active process runs on the CPU of the master, and the standby processes run on the CPU of the subordinate device.
- A process runs at the location where it ran the last time and does not move to any other location during startup or operation.

- The addition of a new node does not impact current active processes. A new active process selects one node with sufficient CPU and memory resources. (You can use the **display cpu-usage** and **display memory** commands to view CPU and memory usage information.)

You can modify the default placement policy in the view you enter by using the **placement program default** command. You can also configure a placement policy for a specific process in the view you enter by using the **placement program** *program-name* [**instance** *instance-name*] command. A placement policy for a process takes precedence over the default process placement policy.

Process placement affinities

You can configure the following settings for a process placement policy to optimize process placement:

- **affinity location-set**—Location affinity, the preference for the process to run on a specific node.
- **affinity location-type**—Location type affinity, the preference for the process to run on a particular type of node. For more information about node types, see "Configuring a location type affinity."
- **affinity program**—Process affinity, the preference for the process to run on the same node as a particular process.
- **affinity self**—Self affinity, the preference for one instance of the process to run on the same node as any other instance of the process.

Affinities include positive affinities (**attract**) and negative affinities (**repulse**), all represented by integers in the range of 1 to 100000.

- The higher the attract value, the stronger the preference.
- The higher the repulse value, the weaker the preference.

Process placement optimization

After you apply new placement policies, the system makes placement decisions based on the new policies, node resources, and topology status. If the new location for an active process is different from the current node, the system changes the state of the process to standby, and uses the standby process on the preferred location as the new active process.

Restrictions and guidelines: process placement configuration

- Configuring process placement on an IRF fabric with only one member device does not change the location of processes. All processes run on the CPU of the IRF member device.
- Configuring process placement on an IRF fabric with multiple member devices places specific active processes to specific CPUs. In case of multiple CPUs, the system performs process redundancy. The number of standby processes and their CPU locations vary by function module. The system by default automatically determines the location for each active process, and process placement optimization is not required. If optimization is required, contact H3C Support to avoid service interruption.
- For an instance of a process, the settings in placement policy view of the instance, in placement policy view of the process, and in default placement policy view are in descending order of priority. For a process, the settings in placement policy view of the process take precedence over the settings in default placement policy view.

- To view the current location of an active process and its predicted new location after optimization, use the **display placement reoptimize** command.

Process placement tasks at a glance

To configure process placement, perform the following tasks:

1. Configuring process placement policy

   Choose the following tasks as needed:

   - Configuring a location affinity
   - Configuring a location type affinity
   - Configuring a process affinity
   - Configuring a self affinity
2. Optimizing process placement

Configuring process placement policy

Configuring a location affinity

1. Enter system view.

   system-view
2. Enter placement process view.
   - Enter default placement process view.

     placement program default
   - Enter specified placement process view.

     placement program { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.
3. Set the location affinity.

   affinity location-set { **slot** *slot-number* }&<1-5> { **attract** *strength* | **default** | **none** | **repulse** *strength* }

   By default, no location affinity is set.

Configuring a location type affinity

About this task

The following location types are available:

- **current**—Current location of the active process, which can be displayed with the **display placement program** command.
- **paired**—Locations of standby processes.
- **primary**—Master device.

Procedure

1. Enter system view.

   system-view
2. Enter placement process view.

- Enter default placement process view.

  placement program default

- Enter specified placement process view.

  placement program { *program-name* [**instance** *instance-name*]

Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Set the location type affinity.

   affinity location-type { **current** | **paired** | **primary** } { **attract** *strength* | **repulse** *strength* | **default** | **none** }

   By default, no location type affinity is set.

Configuring a process affinity

1. Enter system view.

   system-view

2. Enter placement process view.
   - Enter default placement process view.

     placement program default

   - Enter specified placement process view.

     placement program { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Configure the affinity for the process to run on the same location as another process.

   affinity program *program-name* { **attract** *strength* | **default** | **none** | **repulse** *strength* }

   By default, no process affinity is set.

Configuring a self affinity

About this task

A self affinity determines the preference for one instance of a process to run on the same node as any other instance of the process. The self affinity setting does not take effect for a process that has only one instance.

Procedure

1. Enter system view.

   system-view

2. Enter placement process view.
   - Enter default placement process view.

     placement program default

   - Enter specified placement process view.

     placement program { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Configure a self affinity.

   affinity self { **attract** *strength* | **repulse** *strength* | **default** | **none** }

   By default, no self affinity is set.

Optimizing process placement

Restrictions and guidelines

CAUTION:
To avoid neighbor flapping of related protocols, make sure HA features such as NSR or GR are configured for the processes and are stable before optimizing process placement.

To keep the system stable, do not perform any tasks that require process restart when you optimize process placement.

Procedure

1. Enter system view.
   system-view
2. Optimize process placement.
   placement reoptimize

Display and maintenance commands for process placement

Execute **display** commands in any view.

Task	Command
Display service group information.	**display ha service-group** { *program-name* [**instance** *instance-name*] | **all** }
Display the running processes on a specific location.	**display placement location** { **all** | **slot** *slot-number* }
Display process placement policy information.	**display placement policy program** { program-name | **all** | **default** }
Display the location of a process.	**display placement program** { *program-name* | **all** }
Display the predicted location of a process after process placement optimization.	**display placement reoptimize program** { *program-name* [**instance** *instance-name*] | **all** }

H3C S5170-EI Switch Series

Network Management and Monitoring Configuration Guide

Notice

The information in this document is subject to change without notice. All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes network management and monitoring fundamentals and configuration procedures. It describes how to view system information, collect traffic statistics, assess the network performance, synchronize time for all devices with clocks in your network, and use the ping, tracert, and debug commands to check and debug the current network connectivity.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators working with the S5170-EI switch series.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.

>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

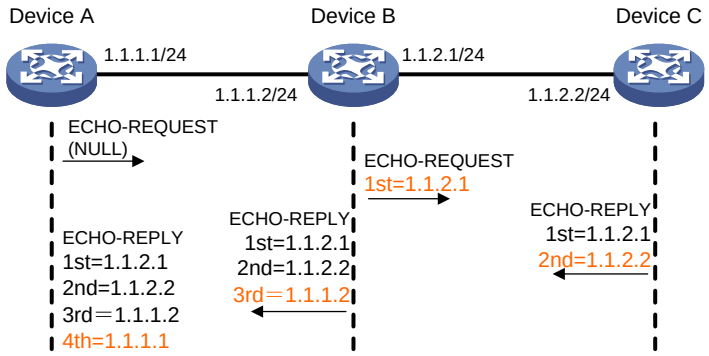
Using ping, tracert, and system debugging

This chapter covers ping, tracert, and information about debugging the system.

Ping

About ping



Use the ping utility to determine if an address is reachable.

Ping sends ICMP echo requests (ECHO-REQUEST) to the destination device. Upon receiving the requests, the destination device responds with ICMP echo replies (ECHO-REPLY) to the source device. The source device outputs statistics about the ping operation, including the number of packets sent, number of echo replies received, and the round-trip time. You can measure the network performance by analyzing these statistics.

You can use the **`ping -r`** command to display the routers through which ICMP echo requests have passed. The test procedure of **`ping -r`** is as shown in Figure 1:

1. The source device (Device A) sends an ICMP echo request to the destination device (Device C) with the RR option empty.
2. The intermediate device (Device B) adds the IP address of its outbound interface (1.1.2.1) to the RR option of the ICMP echo request, and forwards the packet.
3. Upon receiving the request, the destination device copies the RR option in the request and adds the IP address of its outbound interface (1.1.2.2) to the RR option. Then the destination device sends an ICMP echo reply.
4. The intermediate device adds the IP address of its outbound interface (1.1.1.2) to the RR option in the ICMP echo reply, and then forwards the reply.
5. Upon receiving the reply, the source device adds the IP address of its inbound interface (1.1.1.1) to the RR option. The detailed information of routes from Device A to Device C is formatted as: 1.1.1.1 <-> {1.1.1.2; 1.1.2.1} <-> 1.1.2.2.

Figure 1 Ping operation

Using a ping command to test network connectivity

Perform the following tasks in any view:

- Determine if an IPv4 address is reachable.

ping [**ip**] [**-a** *source-ip* | **-c** *count* | **-f** | **-h** *ttl* | **-i** *interface-type interface-number* | **-m** *interval* | **-n** | **-p** *pad* | **-q** | **-r** | **-s** *packet-size* | **-t** *timeout* | **-tos** *tos* | **-v** | **-vpn-instance** *vpn-instance-name*] * *host*

Increase the timeout time (indicated by the **-t** keyword) on a low-speed network.

- Determine if an IPv6 address is reachable.

  ping ipv6 [**-a** *source-ipv6* | **-c** *count* | **-i** *interface-type interface-number* | **-m** *interval* | **-q** | **-s** *packet-size* | **-t** *timeout* | **-tc** *traffic-class* | **-v** | **-vpn-instance** *vpn-instance-name*] * *host*

  Increase the timeout time (indicated by the **-t** keyword) on a low-speed network.

Example: Using the ping utility

Network configuration

As shown in Figure 2, determine if Device A and Device C can reach each other.

Figure 2 Network diagram

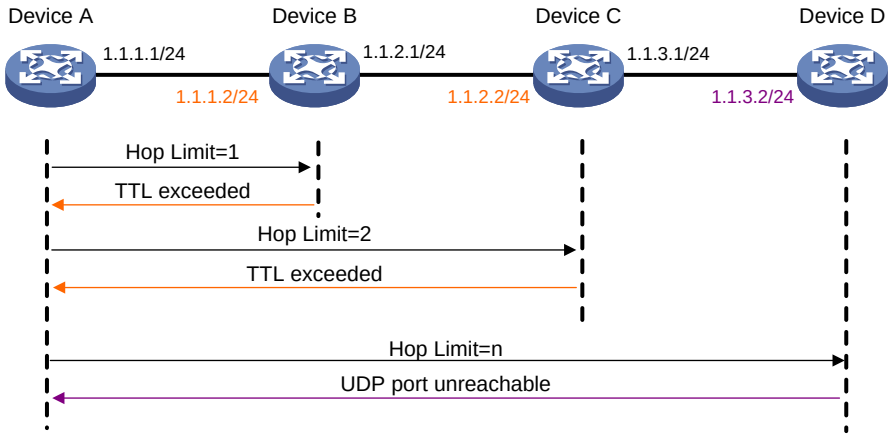
Procedure

Test the connectivity between Device A and Device C.

```
<DeviceA> ping 1.1.2.2
Ping 1.1.2.2 (1.1.2.2): 56 data bytes, press CTRL+C to break
56 bytes from 1.1.2.2: icmp_seq=0 ttl=254 time=2.137 ms
56 bytes from 1.1.2.2: icmp_seq=1 ttl=254 time=2.051 ms
56 bytes from 1.1.2.2: icmp_seq=2 ttl=254 time=1.996 ms
56 bytes from 1.1.2.2: icmp_seq=3 ttl=254 time=1.963 ms
56 bytes from 1.1.2.2: icmp_seq=4 ttl=254 time=1.991 ms

--- Ping statistics for 1.1.2.2 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.963/2.028/2.137/0.062 ms
```

The output shows the following information:



- Device A sends five ICMP packets to Device C and Device A receives five ICMP packets.
- No ICMP packet is lost.
- The route is reachable.

Tracert

About tracert

Tracert (also called Traceroute) enables retrieval of the IP addresses of Layer 3 devices in the path to a destination. In the event of network failure, use tracert to test network connectivity and identify failed nodes.

Figure 3 Tracert operation

Tracert uses received ICMP error messages to get the IP addresses of devices. Tracert works as shown in Figure 3:

1. The source device sends a UDP packet with a TTL value of 1 to the destination device. The destination UDP port is not used by any application on the destination device.
2. The first hop (Device B, the first Layer 3 device that receives the packet) responds by sending a TTL-expired ICMP error message to the source, with its IP address (1.1.1.2) encapsulated. This way, the source device can get the address of the first Layer 3 device (1.1.1.2).
3. The source device sends a packet with a TTL value of 2 to the destination device.
4. The second hop (Device C) responds with a TTL-expired ICMP error message, which gives the source device the address of the second Layer 3 device (1.1.2.2).
5. This process continues until a packet sent by the source device reaches the ultimate destination device. Because no application uses the destination port specified in the packet, the destination device responds with a port-unreachable ICMP message to the source device, with its IP address encapsulated. This way, the source device gets the IP address of the destination device (1.1.3.2).
6. The source device determines that:
   - The packet has reached the destination device after receiving the port-unreachable ICMP message.
   - The path to the destination device is 1.1.1.2 to 1.1.2.2 to 1.1.3.2.

Prerequisites

Before you use a tracert command, perform the tasks in this section.

For an IPv4 network:

- Enable sending of ICMP timeout packets on the intermediate devices (devices between the source and destination devices). If the intermediate devices are H3C devices, execute the **ip ttl-expires enable** command on the devices. For more information about this command, see *Layer 3—IP Services Command Reference*.
- Enable sending of ICMP destination unreachable packets on the destination device. If the destination device is an H3C device, execute the **ip unreachables enable** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

For an IPv6 network:

- Enable sending of ICMPv6 timeout packets on the intermediate devices (devices between the source and destination devices). If the intermediate devices are H3C devices, execute the

ipv6 hoplimit-expires enable command on the devices. For more information about this command, see *Layer 3—IP Services Command Reference*.

- Enable sending of ICMPv6 destination unreachable packets on the destination device. If the destination device is an H3C device, execute the **ipv6 unreachables enable** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

Using a tracert command to identify failed or all nodes in a path

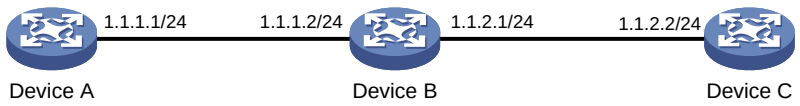
Perform the following tasks in any view:

- Trace the route to an IPv4 destination.

  tracert [**-a** *source-ip* | **-f** *first-ttl* | **-m** *max-ttl* | **-p** *port* | **-q** *packet-number* | **-t** *tos* | **-vpn-instance** *vpn-instance-name* [**-resolve-as** { **global** | **none** | **vpn** }] | **-w** *timeout*] * *host*

- Trace the route to an IPv6 destination.

  tracert ipv6 [**-a** *source-ipv6* | **-f** *first-hop* | **-m** *max-hops* | **-p** *port* | **-q** *packet-number* | **-t** *traffic-class* | **-vpn-instance** *vpn-instance-name* [**-resolve-as** { **global** | **none** | **vpn** }] | **-w** *timeout*] * *host*



Example: Using the tracert utility

Network configuration

As shown in Figure 4, Device A failed to Telnet to Device C.

Test the network connectivity between Device A and Device C. If they cannot reach each other, locate the failed nodes in the network.

Figure 4 Network diagram

Procedure

1. Configure IP addresses for the devices as shown in Figure 4.
2. Configure a static route on Device A.

```
<DeviceA> system-view
[DeviceA] ip route-static 0.0.0.0 0.0.0.0 1.1.1.2
```

3. Test connectivity between Device A and Device C.

```
[DeviceA] ping 1.1.2.2
Ping 1.1.2.2(1.1.2.2): 56 -data bytes, press CTRL+C to break
Request time out
Request time out
Request time out
Request time out
Request time out

--- Ping statistics for 1.1.2.2 ---
5 packet(s) transmitted,0 packet(s) received,100.0% packet loss
```

The output shows that Device A and Device C cannot reach each other.

4. Identify failed nodes:

   # Enable sending of ICMP timeout packets on Device B.

   ```
   <DeviceB> system-view
   [DeviceB] ip ttl-expires enable
   ```

   # Enable sending of ICMP destination unreachable packets on Device C.

   ```
   <DeviceC> system-view
   [DeviceC] ip unreachables enable
   ```

   # Identify failed nodes.

   ```
   [DeviceA] tracert 1.1.2.2
   traceroute to 1.1.2.2 (1.1.2.2) 30 hops at most,40 bytes each packet, press CTRL+C
   to break
    1  1.1.1.2 (1.1.1.2) 1 ms 2 ms 1 ms
    2  * * *
    3  * * *
    4  * * *
    5
   [DeviceA]
   ```

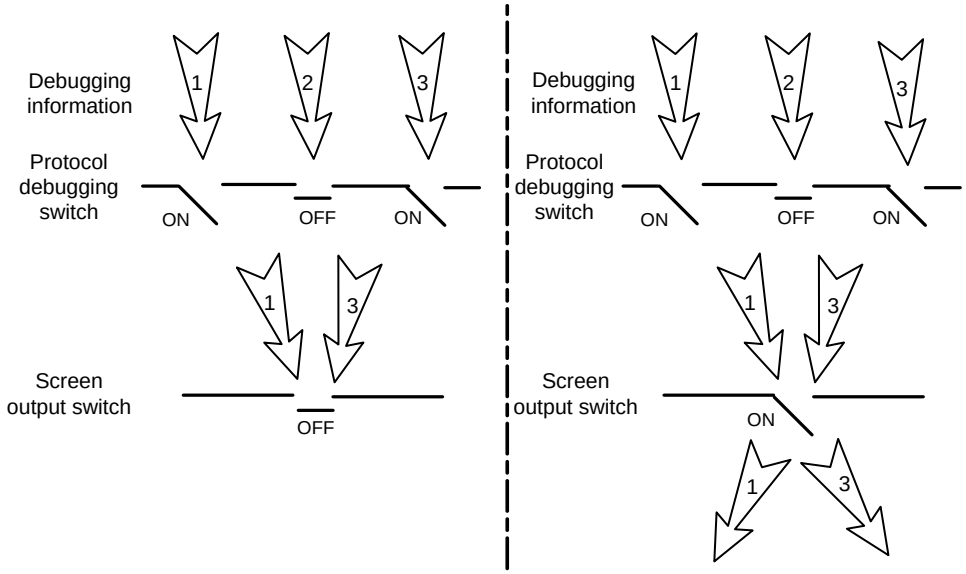
   The output shows that Device A can reach Device B but cannot reach Device C. An error has occurred on the connection between Device B and Device C.

5. To identify the cause of the issue, execute the following commands on Device A and Device C:
   - Execute the **`debugging ip icmp`** command and verify that Device A and Device C can send and receive the correct ICMP packets.
   - Execute the **`display ip routing-table`** command to verify that Device A and Device C have a route to each other.

System debugging

About system debugging

The device supports debugging for the majority of protocols and features, and provides debugging information to help users diagnose errors.



The following switches control the display of debugging information:

- **Module debugging switch**—Controls whether to generate the module-specific debugging information.
- **Screen output switch**—Controls whether to display the debugging information on a certain screen. Use **`terminal monitor`** and **`terminal logging level`** commands to turn on the screen output switch. For more information about these two commands, see *Network Management and Monitoring Command Reference*.

As shown in Figure 5, the device can provide debugging for the three modules 1, 2, and 3. The debugging information can be output on a terminal only when both the module debugging switch and the screen output switch are turned on.

Debugging information is typically displayed on a console. You can also send debugging information to other destinations. For more information, see "Configuring the information center."

Figure 5 Relationship between the module and screen output switch

Debugging a feature module

Restrictions and guidelines

CAUTION:

Output of excessive debugging messages increases the CPU usage and downgrades the system performance. To guarantee system performance, enable debugging only for modules that are in an exceptional condition.

Enable debugging for modules for troubleshooting purposes. When debugging is complete, use the **undo debugging all** command to disable all the debugging functions.

Procedure

1. Enable debugging for a module.

   debugging *module-name* [*option*]

   By default, debugging is disabled for all modules.

   This command is available in user view.

2. (Optional.) Display the enabled debugging features.

   display debugging [*module-name*]

   This command is available in any view.

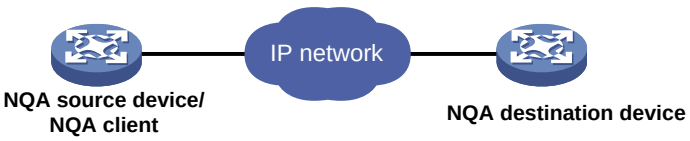
Configuring NQA

About NQA

Network quality analyzer (NQA) allows you to measure network performance, verify the service levels for IP services and applications, and troubleshoot network problems.



NQA operating mechanism

An NQA operation contains a set of parameters such as the operation type, destination IP address, and port number to define how the operation is performed. Each NQA operation is identified by the combination of the administrator name and the operation tag. You can configure the NQA client to run the operations at scheduled time periods.

As shown in Figure 1, the NQA source device (NQA client) sends data to the NQA destination device by simulating IP services and applications to measure network performance.

All types of NQA operations require the NQA client, but only the TCP, UDP echo, UDP jitter, and voice operations require the NQA server. The NQA operations for services that are already provided by the destination device such as FTP do not need the NQA server. You can configure the NQA server to listen and respond to specific IP addresses and ports to meet various test needs.

Figure 1 Network diagram

After starting an NQA operation, the NQA client periodically performs the operation at the interval specified by using the **`frequency`** command.

You can set the number of probes the NQA client performs in an operation by using the **`probe count`** command. For the voice and path jitter operations, the NQA client performs only one probe per operation and the **`probe count`** command is not available.

Collaboration with Track

NQA can collaborate with the Track module to notify application modules of state or performance changes so that the application modules can take predefined actions.

The NQA + Track collaboration is available for the following application modules:

The NQA + Track collaboration is available for the following application modules:

- VRRP.
- Static routing.
- Policy-based routing.
- Traffic redirecting.
- Smart Link.

The following describes how a static route destined for 192.168.0.88 is monitored through collaboration:

1. NQA monitors the reachability to 192.168.0.88.

2. When 192.168.0.88 becomes unreachable, NQA notifies the Track module of the change.
3. The Track module notifies the static routing module of the state change.
4. The static routing module sets the static route to invalid according to a predefined action.

For more information about collaboration, see *High Availability Configuration Guide*.

Threshold monitoring

Threshold monitoring enables the NQA client to take a predefined action when the NQA operation performance metrics violate the specified thresholds.

Table 1 describes the relationships between performance metrics and NQA operation types.

Table 1 Performance metrics and NQA operation types

Performance metric	NQA operation types that can gather the metric
Probe duration	All NQA operation types except UDP jitter, UDP tracert, path jitter, and voice
Number of probe failures	All NQA operation types except UDP jitter, UDP tracert, path jitter, and voice
Round-trip time	ICMP jitter, UDP jitter, and voice
Number of discarded packets	ICMP jitter, UDP jitter, and voice
One-way jitter (source-to-destination or destination-to-source)	ICMP jitter, UDP jitter, and voice
One-way delay (source-to-destination or destination-to-source)	ICMP jitter, UDP jitter, and voice
Calculated Planning Impairment Factor (ICPIF) (see "Configuring the voice operation")	Voice
Mean Opinion Scores (MOS) (see "Configuring the voice operation")	Voice

NQA templates

An NQA template is a set of parameters (such as destination address and port number) that defines how an NQA operation is performed. Features can use the NQA template to collect statistics.

You can create multiple NQA templates on the NQA client. Each template must be identified by a unique template name.

Restrictions and guidelines: NQA configuration

To avoid probe failures, follow these restrictions and guidelines when configuring the listening ports on the NQA client and NQA server:

- Do not specify a well-known port.
- Make sure the specified port number is not used by any services on the device.
  - To obtain the IPv4 addresses and the port numbers in use on this device, see the **Local Addr:port** field in the output from the **`display tcp`** and **`display udp`** commands.

- To obtain the IPv6 addresses and the port numbers in use on this device, see the **LAddr->port** field in the output from the **`display ipv6 tcp`** and **`display ipv6 udp`** commands.

If the source IP address of NQA probe packets has been NATed through the Easy IP feature, the local device might fail to receive NQA response packets, resulting in NQA operation failure. As a best practice, use the **`source interface`**, **`source ip`**, or **`source ipv6`** command to specify the source IP address of NQA probe packets to prevent the source IP address from being translated by NAT. In the output from the **`display nat all`** command, if the **NAT address group information** field contains the output interface IP address of NQA probe packets, or the **NAT outbound information** field contains the output interface of NQA probe packets, the source IP address of NQA probe packets will be NATed by the Easy IP feature. Avoid specifying the IP address and interface when configuring the source IP address. For more information about Easy IP, see NAT configuration in *Layer 3—IP Services Configuration Guide*.

The destination port configured for the operation (with the **`destination port`** command) on the NQA client must be the same as the listening port configured on the server.

During the initial startup phase, the device might not have generated route entries or ARP table entries to reach the destination address of the operation, or the probe packet output interface might not be up, which can result in NQA operation failure.

For latency operation results to be accurate, synchronize time between the source and the destination with an accuracy higher than or equal to the operation result calculation accuracy.

NQA tasks at a glance

To configure NQA, perform the following tasks:

1. Configuring the NQA server

   Perform this task on the destination device before you configure the TCP, UDP echo, UDP jitter, and voice operations.
2. Enabling the NQA client
3. Configuring NQA operations or NQA templates

   Choose the following tasks as needed:

   - Configuring NQA operations on the NQA client
   - Configuring NQA templates on the NQA client

   After you configure an NQA operation, you can schedule the NQA client to run the NQA operation.

   An NQA template does not run immediately after it is configured. The template creates and run the NQA operation only when it is required by the feature to which the template is applied.

Configuring the NQA server

Restrictions and guidelines

To perform TCP, UDP echo, UDP jitter, and voice operations, you must configure the NQA server on the destination device. The NQA server listens and responds to requests on the specified IP addresses and ports.

You can configure multiple TCP or UDP listening services on an NQA server, where each corresponds to a specific IP address and port number.

The IP address, port number, and VPN instance for a listening service must be unique on the NQA server and match the configuration on the NQA client.

Procedure

1. Enter system view.
   system-view
2. Enable the NQA server.
   nqa server enable
   By default, the NQA server is disabled.
3. Configure a TCP listening service.
   nqa server tcp-connect *ip-address port-number* [**vpn-instance** *vpn-instance-name*] [**tos** *tos*]
   This task is required for only TCP and DLSw operations. For the DLSw operation, the port number for the TCP listening service must be 2065.
4. Configure a UDP listening service.
   nqa server udp-echo *ip-address port-number* [**vpn-instance** *vpn-instance-name*] [**tos** *tos*]
   This task is required for only UDP echo, UDP jitter, and voice operations.

Enabling the NQA client

1. Enter system view.
   system-view
2. Enable the NQA client.
   nqa agent enable
   By default, the NQA client is enabled.
   The NQA client configuration takes effect after you enable the NQA client.

Configuring NQA operations on the NQA client

NQA operations tasks at a glance

To configure NQA operations, perform the following tasks:

1. Configuring an NQA operation
   - Configuring the ICMP echo operation
   - Configuring the ICMP jitter operation
   - Configuring the DHCP operation
   - Configuring the DNS operation
   - Configuring the FTP operation
   - Configuring the HTTP operation
   - Configuring the UDP jitter operation
   - Configuring the SNMP operation
   - Configuring the TCP operation
   - Configuring the UDP echo operation
   - Configuring the UDP tracert operation
   - Configuring the voice operation
   - Configuring the DLSw operation

- Configuring the path jitter operation

2. (Optional.) Configuring optional parameters for the NQA operation
3. (Optional.) Configuring the collaboration feature
4. (Optional.) Configuring threshold monitoring
5. (Optional.) Configuring the NQA statistics collection feature
6. (Optional.) Configuring the saving of NQA history records
7. Scheduling the NQA operation on the NQA client

Configuring the ICMP echo operation

About this task

The ICMP echo operation measures the reachability of a destination device. It has the same function as the **ping** command, but provides more output information. In addition, if multiple paths exist between the source and destination devices, you can specify the next hop for the ICMP echo operation.

The ICMP echo operation sends an ICMP echo request to the destination device per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the ICMP echo type and enter its view.

   type icmp-echo

4. Specify the destination IP address for ICMP echo requests.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

5. Specify the source IP address for ICMP echo requests. Choose one option as needed:

   - Use the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

     The specified source interface must be up.

   - Specify the source IPv4 address.

     source ip *ip-address*

     By default, the source IPv4 address of ICMP echo requests is the primary IPv4 address of their output interface.

     The specified source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   - Specify the source IPv6 address.

     source ipv6 *ipv6-address*

     By default, the source IPv6 address of ICMP echo requests is the primary IPv6 address of their output interface.

The specified source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the output interface or the next hop IP address for ICMP echo requests. Choose one option as needed: (If you configure both the output interface and next hop IP address, only the next hop IP address takes effect. To avoid probe failure, make sure the IP address belongs to a directly connected next hop.)
   - Specify the output interface for ICMP echo requests.
     out interface *interface-type interface-number*
     By default, the output interface for ICMP echo requests is not specified. The NQA client determines the output interface based on the routing table lookup.
   - Specify the next hop IPv4 address.
     next-hop ip *ip-address*
     By default, no next hop IPv4 address is specified.
   - Specify the next hop IPv6 address.
     next-hop ipv6 *ipv6-address*
     By default, no next hop IPv6 address is specified.
7. (Optional.) Set the payload size for each ICMP echo request.
   data-size *size*
   The default payload size is 100 bytes.
8. (Optional.) Specify the payload fill string for ICMP echo requests.
   data-fill *string*
   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the ICMP jitter operation

About this task

The ICMP jitter operation measures unidirectional and bidirectional jitters. The operation result helps you to determine whether the network can carry jitter-sensitive services such as real-time voice and video services.

The ICMP jitter operation works as follows:

1. The NQA client sends ICMP packets to the destination device.
2. The destination device time stamps each packet it receives, and then sends the packet back to the NQA client.
3. Upon receiving the responses, the NQA client calculates the jitter according to the timestamps.

The ICMP jitter operation sends a number of ICMP packets to the destination device per probe. The number of packets to send is determined by using the **probe packet-number** command.

Restrictions and guidelines

The **display nqa history** command does not display the results or statistics of the ICMP jitter operation. To view the results or statistics of the operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.

nqa entry *admin-name operation-tag*

3. Specify the ICMP jitter type and enter its view.
   type icmp-jitter
4. Specify the destination IP address for ICMP packets.
   destination ip *ip-address*

   By default, no destination IP address is specified.
5. Set the number of ICMP packets sent per probe.
   probe packet-number *number*

   The default setting is 10.
6. Set the interval for sending ICMP packets.
   probe packet-interval *interval*

   The default setting is 20 milliseconds.
7. Specify how long the NQA client waits for a response from the server before it regards the response times out.
   probe packet-timeout *timeout*

   The default setting is 3000 milliseconds.
8. Specify the source IP address for ICMP packets.
   source ip *ip-address*

   By default, the source IP address of ICMP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no ICMP packets can be sent out.

Configuring the DHCP operation

About this task

The DHCP operation measures whether or not the DHCP server can respond to client requests. DHCP also measures the amount of time it takes the NQA client to obtain an IP address from a DHCP server.

The NQA client simulates the DHCP relay agent to forward DHCP requests for IP address acquisition from the DHCP server. The interface that performs the DHCP operation does not change its IP address. When the DHCP operation completes, the NQA client sends a packet to release the obtained IP address.

The DHCP operation acquires an IP address from the DHCP server per probe.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the DHCP type and enter its view.
   type dhcp
4. Specify the IP address of the DHCP server as the destination IP address of DHCP packets.
   destination ip *ip-address*

   By default, no destination IP address is specified.
5. Specify the output interface for DHCP request packets.

out interface *interface-type interface-number*

By default, the NQA client determines the output interface based on the routing table lookup.

6. Specify the source IP address of DHCP request packets.

   source ip *ip-address*

   By default, the source IP address of DHCP request packets is the primary IP address of their output interface.

   The specified source IP address must be the IP address of a local interface, and the local interface must be up. Otherwise, no probe packets can be sent out.

Configuring the DNS operation

About this task

The DNS operation simulates domain name resolution, and it measures the time for the NQA client to resolve a domain name into an IP address through a DNS server. The obtained DNS entry is not saved.

The DNS operation resolves a domain name into an IP address per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the DNS type and enter its view.

   type dns

4. Specify the IP address of the DNS server as the destination IP address of DNS packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

5. Specify the domain name to be translated.

   resolve-target *domain-name*

   By default, no domain name is specified.

Configuring the FTP operation

About this task

The FTP operation measures the time for the NQA client to transfer a file to or download a file from an FTP server.

The FTP operation uploads or downloads a file from an FTP server per probe.

Restrictions and guidelines

To upload (**put**) a file to the FTP server, use the **filename** command to specify the name of the file you want to upload. The file must exist on the NQA client.

To download (**get**) a file from the FTP server, include the name of the file you want to download in the **url** command. The file must exist on the FTP server. The NQA client does not save the file obtained from the FTP server.

Use a small file for the FTP operation. A big file might result in transfer failure because of timeout, or might affect other services because of the amount of network bandwidth it occupies.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the FTP type and enter its view.
   type ftp
4. Specify an FTP login username.
   username *username*
   By default, no FTP login username is specified.
5. Specify an FTP login password.
   password { **cipher** | **simple** } *string*
   By default, no FTP login password is specified.
6. Specify the source IP address for FTP request packets.
   source ip *ip-address*
   By default, the source IP address of FTP request packets is the primary IP address of their output interface.
   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no FTP requests can be sent out.
7. Set the data transmission mode.
   mode { **active** | **passive** }
   The default mode is **active**.
8. Specify the FTP operation type.
   operation { **get** | **put** }
   The default FTP operation type is **get**.
9. Specify the destination URL for the FTP operation.
   url *url*
   By default, no destination URL is specified for an FTP operation.
   Enter the URL in one of the following formats:
   - ftp://*host*/*filename*.
   - ftp://*host:port*/*filename*.

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, ftp://[2001::1]/test. The *filename* argument is required only for the **get** operation.
10. Specify the name of the file to be uploaded.
    filename *file-name*
    By default, no file is specified.
    This task is required only for the **put** operation.
    The configuration does not take effect for the **get** operation.

Configuring the HTTP operation

About this task

The HTTP operation measures the time for the NQA client to obtain responses from an HTTP server.

The HTTP operation supports the following operation types:

- **Get**—Retrieves data such as a Web page from the HTTP server.
- **Post**—Sends data to the HTTP server for processing.
- **Raw**—Sends a user-defined HTTP request to the HTTP server. You must manually configure the content of the HTTP request to be sent.

The HTTP operation completes the operation of the specified type per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the HTTP type and enter its view.

   type http

4. Specify the destination URL for the HTTP operation.

   url *url*

   By default, no destination URL is specified for an HTTP operation.

   Enter the URL in one of the following formats:

   - http://*host*/*resource*
   - http://*host:port/resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, http://[2001::1]/test.

5. Specify an HTTP login username.

   username *username*

   By default, no HTTP login username is specified.

6. Specify an HTTP login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTP login password is specified.

7. Specify the HTTP version.

   version { **v1.0** | **v1.1** }

   By default, HTTP 1.0 is used.

8. Specify the HTTP operation type.

   operation { **get** | **post** | **raw** }

   The default HTTP operation type is **get**.

   If you set the operation type to **raw**, the client pads the content configured in raw request view to the HTTP request to send to the HTTP server.

9. Configure the HTTP raw request.

   a. Enter raw request view.

   raw-request

   Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

   By default, no request content is configured.

To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

c. Save the input and return to HTTP operation view:

quit

This step is required only when the operation type is set to **raw**.

10. Specify the source IP address for the HTTP packets.

source ip *ip-address*

By default, the source IP address of HTTP packets is the primary IP address of their output interface.

The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no request packets can be sent out.

Configuring the UDP jitter operation

About this task

The UDP jitter operation measures unidirectional and bidirectional jitters. The operation result helps you determine whether the network can carry jitter-sensitive services such as real-time voice and video services.

The UDP jitter operation works as follows:

1. The NQA client sends UDP packets to the destination port.
2. The destination device time stamps each packet it receives, and then sends the packet back to the NQA client.
3. Upon receiving the responses, the NQA client calculates the jitter according to the timestamps.

The UDP jitter operation sends a number of UDP packets to the destination device per probe. The number of packets to send is determined by using the **probe packet-number** command.

The UDP jitter operation requires both the NQA server and the NQA client. Before you perform the UDP jitter operation, configure the UDP listening service on the NQA server. For more information about UDP listening service configuration, see "Configuring the NQA server."

Restrictions and guidelines

To ensure successful UDP jitter operations and avoid affecting existing services, do not perform the operations on well-known ports from 1 to 1023.

The **display nqa history** command does not display the results or statistics of the UDP jitter operation. To view the results or statistics of the UDP jitter operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the UDP jitter type and enter its view.

   type udp-jitter

4. Specify the destination IP address for UDP packets.

   destination ip *ip-address*

By default, no destination IP address is specified.

The destination IP address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

6. Specify the source IP address for UDP packets.

   source ip *ip-address*

   By default, the source IP address of UDP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

7. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. Set the number of UDP packets sent per probe.

   probe packet-number *number*

   The default setting is 10.

9. Set the interval for sending UDP packets.

   probe packet-interval *interval*

   The default setting is 20 milliseconds.

10. Specify how long the NQA client waits for a response from the server before it regards the response times out.

    probe packet-timeout *timeout*

    The default setting is 3000 milliseconds.

11. (Optional.) Set the payload size for each UDP packet.

    data-size *size*

    The default payload size is 100 bytes.

12. (Optional.) Specify the payload fill string for UDP packets.

    data-fill *string*

    The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the SNMP operation

About this task

The SNMP operation tests whether the SNMP service is available on an SNMP agent.

The SNMP operation sends one SNMPv1 packet, one SNMPv2c packet, and one SNMPv3 packet to the SNMP agent per probe.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the SNMP type and enter its view.
   type snmp
4. Specify the destination address for SNMP packets.
   destination ip *ip-address*
   By default, no destination IP address is specified.
5. Specify the source IP address for SNMP packets.
   source ip *ip-address*
   By default, the source IP address of SNMP packets is the primary IP address of their output interface.
   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no SNMP packets can be sent out.
6. Specify the source port number for SNMP packets.
   source port *port-number*
   By default, the NQA client randomly picks an unused port as the source port when the operation starts.
   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.
7. Specify the community name carried in the SNMPv1 and SNMPv2c packets.
   community read { **cipher** | **simple** } *community-name*
   By default, the SNMPv1 and SNMPv2c packets carry community name **public**.
   Make sure the specified community name is the same as the community name configured on the SNMP agent.

Configuring the TCP operation

About this task

The TCP operation measures the time for the NQA client to establish a TCP connection to a port on the NQA server.

The TCP operation requires both the NQA server and the NQA client. Before you perform a TCP operation, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "Configuring the NQA server."

The TCP operation sets up a TCP connection per probe.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the TCP type and enter its view.
   type tcp
4. Specify the destination address for TCP packets.

destination ip *ip-address*

By default, no destination IP address is specified.

The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

5. Specify the destination port for TCP packets.

   destination port *port-number*

   By default, no destination port number is configured.

   The destination port number must be the same as the port number of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

6. Specify the source IP address for TCP packets.

   source ip *ip-address*

   By default, the source IP address of TCP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no TCP packets can be sent out.

Configuring the UDP echo operation

About this task

The UDP echo operation measures the round-trip time between the client and a UDP port on the NQA server.

The UDP echo operation requires both the NQA server and the NQA client. Before you perform a UDP echo operation, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "Configuring the NQA server."

The UDP echo operation sends a UDP packet to the destination device per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the UDP echo type and enter its view.

   type udp-echo

4. Specify the destination address for UDP packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

6. Specify the source IP address for UDP packets.

   source ip *ip-address*

   By default, the source IP address of UDP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

7. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. (Optional.) Set the payload size for each UDP packet.

   data-size *size*

   The default setting is 100 bytes.

9. (Optional.) Specify the payload fill string for UDP packets.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the UDP tracert operation

About this task

The UDP tracert operation determines the routing path from the source device to the destination device.

The UDP tracert operation sends a UDP packet to a hop along the path per probe.

Restrictions and guidelines

The UDP tracert operation is not supported on IPv6 networks. To determine the routing path that the IPv6 packets traverse from the source to the destination, use the **tracert ipv6** command. For more information about the command, see *Network Management and Monitoring Command Reference.*

Prerequisites

Before you configure the UDP tracert operation, you must perform the following tasks:

- Enable sending ICMP time exceeded messages on the intermediate devices between the source and destination devices. If the intermediate devices are H3C devices, use the **ip ttl-expires enable** command.
- Enable sending ICMP destination unreachable messages on the destination device. If the destination device is an H3C device, use the **ip unreachables enable** command.

  For more information about the **ip ttl-expires enable** and **ip unreachables enable** commands, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the UDP tracert operation type and enter its view.

type udp-tracert

4. Specify the destination device for the operation. Choose one option as needed:
   - Specify the destination device by its host name.

     destination host *host-name*

     By default, no destination host name is specified.
   - Specify the destination device by its IP address.

     destination ip *ip-address*

     By default, no destination IP address is specified.
5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, the destination port number is 33434.

   This port number must be an unused number on the destination device, so that the destination device can reply with ICMP port unreachable messages.
6. Specify an output interface for UDP packets.

   out interface *interface-type interface-number*

   By default, the NQA client determines the output interface based on the routing table lookup.
7. Specify the source IP address for UDP packets.
   - Specify the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the source IP address of UDP packets is the primary IP address of their output interface.
   - Specify the source IP address.

     source ip *ip-address*

     The specified source interface must be up. The source IP address must be the IP address of a local interface, and the local interface must be up. Otherwise, no probe packets can be sent out.
8. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.
9. Set the maximum number of consecutive probe failures.

   max-failure *times*

   The default setting is 5.
10. Set the initial TTL value for UDP packets.

    init-ttl *value*

    The default setting is 1.
11. (Optional.) Set the payload size for each UDP packet.

    data-size *size*

    The default setting is 100 bytes.
12. (Optional.) Enable the no-fragmentation feature.

    no-fragment enable

    By default, the no-fragmentation feature is disabled.

Configuring the voice operation

About this task

The voice operation measures VoIP network performance.

The voice operation works as follows:

1. The NQA client sends voice packets at sending intervals to the destination device (NQA server).

   The voice packets are of one of the following codec types:

   - G.711 A-law.
   - G.711 μ-law.
   - G.729 A-law.
2. The destination device time stamps each voice packet it receives and sends it back to the source.
3. Upon receiving the packet, the source device calculates the jitter and one-way delay based on the timestamp.

The voice operation sends a number of voice packets to the destination device per probe. The number of packets to send per probe is determined by using the **probe packet-number** command.

The following parameters that reflect VoIP network performance can be calculated by using the metrics gathered by the voice operation:

- **Calculated Planning Impairment Factor (ICPIF)**—Measures impairment to voice quality on a VoIP network. It is decided by packet loss and delay. A higher value represents a lower service quality.
- **Mean Opinion Scores (MOS)**—A MOS value can be evaluated by using the ICPIF value, in the range of 1 to 5. A higher value represents a higher service quality.

The evaluation of voice quality depends on users' tolerance for voice quality. For users with higher tolerance for voice quality, use the **advantage-factor** command to set an advantage factor. When the system calculates the ICPIF value, it subtracts the advantage factor to modify ICPIF and MOS values for voice quality evaluation.

The voice operation requires both the NQA server and the NQA client. Before you perform a voice operation, configure a UDP listening service on the NQA server. For more information about UDP listening service configuration, see "Configuring the NQA server."

Restrictions and guidelines

To ensure successful voice operations and avoid affecting existing services, do not perform the operations on well-known ports from 1 to 1023.

The **display nqa history** command does not display the results or statistics of the voice operation. To view the results or statistics of the voice operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*
3. Specify the voice type and enter its view.

type voice

4. Specify the destination IP address for voice packets.

   destination ip *ip-address*

   By default, no destination IP address is configured.

   The destination IP address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the destination port number for voice packets.

   destination port *port-number*

   By default, no destination port number is configured.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

6. Specify the source IP address for voice packets.

   source ip *ip-address*

   By default, the source IP address of voice packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no voice packets can be sent out.

7. Specify the source port number for voice packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. Configure the basic voice operation parameters.
   - Specify the codec type.

     codec-type { **g711a** | **g711u** | **g729a** }

     By default, the codec type is G.711 A-law.
   - Set the advantage factor for calculating MOS and ICPIF values.

     advantage-factor *factor*

     By default, the advantage factor is 0.

9. Configure the probe parameters for the voice operation.
   - Set the number of voice packets to be sent per probe.

     probe packet-number *number*

     The default setting is 1000.
   - Set the interval for sending voice packets.

     probe packet-interval *interval*

     The default setting is 20 milliseconds.
   - Specify how long the NQA client waits for a response from the server before it regards the response times out.

     probe packet-timeout *timeout*

     The default setting is 5000 milliseconds.

10. Configure the payload parameters.

    a. Set the payload size for voice packets.

    data-size *size*

By default, the voice packet size varies by codec type. The default packet size is 172 bytes for G.711A-law and G.711 μ-law codec type, and 32 bytes for G.729 A-law codec type.

b. (Optional.) Specify the payload fill string for voice packets.

data-fill *string*

The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the DLSw operation

About this task

The DLSw operation measures the response time of a DLSw device.

It sets up a DLSw connection to the DLSw device per probe.

Restrictions and guidelines

For the DLSw operation to succeed, configure the **nqa server tcp-connect** command on the NQA server and make sure the port number for the TCP listening service is 2065.

Procedure

1. Enter system view.

system-view

2. Create an NQA operation and enter NQA operation view.

nqa entry *admin-name operation-tag*

3. Specify the DLSw type and enter its view.

type dlsw

4. Specify the destination IP address for the probe packets.

destination ip *ip-address*

By default, no destination IP address is specified.

5. Specify the source IP address for the probe packets.

source ip *ip-address*

By default, the source IP address of the probe packets is the primary IP address of their output interface.

The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the path jitter operation

About this task

The path jitter operation measures the jitter, negative jitters, and positive jitters from the NQA client to each hop on the path to the destination.

The path jitter operation performs the following steps per probe:

1. Obtains the path from the NQA client to the destination through tracert. A maximum of 64 hops can be detected.

2. Sends a number of ICMP echo requests to each hop along the path. The number of ICMP echo requests to send is set by using the **probe packet-number** command.

Prerequisites

Before you configure the path jitter operation, you must perform the following tasks:

- Enable sending ICMP time exceeded messages on the intermediate devices between the source and destination devices. If the intermediate devices are H3C devices, use the **ip ttl-expires enable** command.
- Enable sending ICMP destination unreachable messages on the destination device. If the destination device is an H3C device, use the **ip unreachables enable** command.

  For more information about the **ip ttl-expires enable** and **ip unreachables enable** commands, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*
3. Specify the path jitter type and enter its view.

   type path-jitter
4. Specify the destination IP address for ICMP echo requests.

   destination ip *ip-address*

   By default, no destination IP address is specified.
5. Specify the source IP address for ICMP echo requests.

   source ip *ip-address*

   By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no ICMP echo requests can be sent out.
6. Configure the probe parameters for the path jitter operation.
   a. Set the number of ICMP echo requests to be sent per probe.

      probe packet-number *number*

      The default setting is 10.
   b. Set the interval for sending ICMP echo requests.

      probe packet-interval *interval*

      The default setting is 20 milliseconds.
   c. Specify how long the NQA client waits for a response from the server before it regards the response times out.

      probe packet-timeout *timeout*

      The default setting is 3000 milliseconds.
7. (Optional.) Specify an LSR path.

   lsr-path *ip-address*&<1-8>

   By default, no LSR path is specified.

   The path jitter operation uses tracert to detect the LSR path to the destination, and sends ICMP echo requests to each hop on the LSR path.
8. Perform the path jitter operation only on the destination address.

   target-only

   By default, the path jitter operation is performed on each hop on the path to the destination.
9. (Optional.) Set the payload size for each ICMP echo request.

   data-size *size*

   The default setting is 100 bytes.

10. (Optional.) Specify the payload fill string for ICMP echo requests.

    data-fill *string*

    The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring optional parameters for the NQA operation

Restrictions and guidelines

The parameter settings take effect only on the current operation.

The supported parameters vary by NQA operation type. For information about supported parameters, see NQA commands in *Network Management and Monitoring Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Specify an NQA operation type and enter its view.

   type { **dhcp** | **dlsw** | **dns** | **ftp** | **http** | **icmp-echo** | **icmp-jitter** | **path-jitter** | **snmp** | **tcp** | **udp-echo** | **udp-jitter** | **udp-tracert** | **voice** }

4. Configure a description for the operation.

   description *text*

   By default, no description is configured.

5. Set the interval at which the NQA operation repeats.

   frequency *interval*

   For a voice or path jitter operation, the default setting is 60000 milliseconds.

   For other types of operations, the default setting is 0 milliseconds, and only one operation is performed.

   When the interval expires, but the operation is not completed or is not timed out, the next operation does not start.

6. Specify the probe times.

   probe count *times*

   In an UDP tracert operation, the NQA client performs three probes to each hop to the destination by default.

   In other types of operations, the NQA client performs one probe to the destination per operation by default.

   This command is not available for the voice and path jitter operations. Each of these operations performs only one probe.

7. Set the probe timeout time.

   probe timeout *timeout*

   The default setting is 3000 milliseconds.

8. Set the maximum number of hops that the probe packets can traverse.

   ttl *value*

   The default setting is 30 for probe packets of the UDP tracert operation, and is 20 for probe packets of other types of operations.

9. Set the ToS value in the IP header of the probe packets.

   tos *value*

The default setting is 0.

10. Enable the routing table bypass feature.

    route-option bypass-route

    By default, the routing table bypass feature is disabled.

    This command does not take effect if the destination address of the NQA operation is an IPv6 address.

11. Specify the VPN instance where the operation is performed.

    vpn-instance *vpn-instance-name*

    By default, the operation is performed on the public network.

Configuring the collaboration feature

About this task

Collaboration is implemented by associating a reaction entry of an NQA operation with a track entry. The reaction entry monitors the NQA operation. If the number of operation failures reaches the specified threshold, the configured action is triggered.

Restrictions and guidelines

The collaboration feature is not available for the following types of operations:

- ICMP jitter operation.
- UDP jitter operation.
- UDP tracert operation.
- Voice operation.
- Path jitter operation.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Configure a reaction entry.

   reaction *item-number* **checked-element probe-fail threshold-type consecutive** *consecutive-occurrences* **action-type trigger-only**

   You cannot modify the content of an existing reaction entry.

4. Return to system view.

   quit

5. Associate Track with NQA.

   For information about the configuration, see *High Availability Configuration Guide*.

6. Associate Track with an application module.

   For information about the configuration, see *High Availability Configuration Guide*.

Configuring threshold monitoring

About this task

This feature allows you to monitor the NQA operation running status.

An NQA operation supports the following threshold types:

- **average**—If the average value for the monitored performance metric either exceeds the upper threshold or goes below the lower threshold, a threshold violation occurs.
- **accumulate**—If the total number of times that the monitored performance metric is out of the specified value range reaches or exceeds the specified threshold, a threshold violation occurs.
- **consecutive**—If the number of consecutive times that the monitored performance metric is out of the specified value range reaches or exceeds the specified threshold, a threshold violation occurs.

Threshold violations for the average or accumulate threshold type are determined on a per NQA operation basis. The threshold violations for the consecutive type are determined from the time the NQA operation starts.

The following actions might be triggered:

- **none**—NQA displays results only on the terminal screen. It does not send traps to the NMS.
- **trap-only**—NQA displays results on the terminal screen, and meanwhile it sends traps to the NMS.

  To send traps to the NMS, the NMS address must be specified by using the **snmp-agent target-host** command. For more information about the command, see *Network Management and Monitoring Command Reference*.
- **trigger-only**—NQA displays results on the terminal screen, and meanwhile triggers other modules for collaboration.

In a reaction entry, configure a monitored element, a threshold type, and an action to be triggered to implement threshold monitoring.

The state of a reaction entry can be invalid, over-threshold, or below-threshold.

- Before an NQA operation starts, the reaction entry is in invalid state.
- If the threshold is violated, the state of the entry is set to over-threshold. Otherwise, the state of the entry is set to below-threshold.

Restrictions and guidelines

The threshold monitoring feature is not available for the path jitter operations.

Procedure

1. Enter system view.

   system-view
2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*
3. Enable sending traps to the NMS when specific conditions are met.

   reaction trap { **path-change** | **probe-failure** *consecutive-probe-failures* | **test-complete** | **test-failure** [*accumulate-probe-failures*] }

   By default, no traps are sent to the NMS.

   The ICMP jitter, UDP jitter, and voice operations support only the **test-complete** keyword.

   The following parameters are not available for the UDP tracert operation:

   - The **probe-failure** *consecutive-probe-failures* option.
   - The *accumulate-probe-failures* argument.
4. Configure threshold monitoring. Choose the options to configure as needed:

   - Monitor the operation duration.

     reaction *item-number* **checked-element probe-duration threshold-type** { **accumulate** *accumulate-occurrences* | **average** |

consecutive *consecutive-occurrences* } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

This reaction entry is not supported in the ICMP jitter, UDP jitter, UDP tracert, or voice operations

- Monitor failure times.

  reaction *item-number* **checked-element probe-fail threshold-type** { **accumulate** *accumulate-occurrences* | **consecutive** *consecutive-occurrences* } [**action-type** { **none** | **trap-only** }]

  This reaction entry is not supported in the ICMP jitter, UDP jitter, UDP tracert, or voice operations.

- Monitor the round-trip time.

  reaction *item-number* **checked-element rtt threshold-type** { **accumulate** *accumulate-occurrences* | **average** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor packet loss.

  reaction *item-number* **checked-element packet-loss threshold-type accumulate** *accumulate-occurrences* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the one-way jitter.

  reaction *item-number* **checked-element** { **jitter-ds** | **jitter-sd** } **threshold-type** { **accumulate** *accumulate-occurrences* | **average** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the one-way delay.

  reaction *item-number* **checked-element** { **owd-ds** | **owd-sd** } **threshold-value** *upper-threshold lower-threshold*

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the ICPIF value.

  reaction *item-number* **checked-element icpif threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the voice operation supports this reaction entry.

- Monitor the MOS value.

  reaction *item-number* **checked-element mos threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the voice operation supports this reaction entry.

The DNS operation does not support the action of sending trap messages. For the DNS operation, the action type can only be **none**.

Configuring the NQA statistics collection feature

About this task

NQA forms statistics within the same collection interval as a statistics group. To display information about the statistics groups, use the **display nqa statistics** command.

When the maximum number of statistics groups is reached, the NQA client deletes the oldest statistics group to save a new one.

A statistics group is automatically deleted when its hold time expires.

Restrictions and guidelines

The NQA statistics collection feature is not available for the UDP tracert operations.

If you use the **frequency** command to set the interval to 0 milliseconds for an NQA operation, NQA does not generate any statistics group for the operation.

Procedure

1. Enter system view.
   system-view
2. Enter the view of an existing NQA operation.
   nqa entry *admin-name operation-tag*
3. Set the statistics collection interval.
   statistics interval *interval*
   The default setting is 60 minutes.
4. Set the maximum number of statistics groups that can be saved.
   statistics max-group *number*
   By default, the NQA client can save a maximum of two statistics groups for an operation.
   To disable the NQA statistics collection feature, set the *number* argument to 0.
5. Set the hold time of statistics groups.
   statistics hold-time *hold-time*
   The default setting is 120 minutes.

Configuring the saving of NQA history records

About this task

This task enables the NQA client to save NQA history records. You can use the **display nqa history** command to display the NQA history records.

Restrictions and guidelines

The NQA history record saving feature is not available for the following types of operations:

- ICMP jitter operation.
- UDP jitter operation.
- Voice operation.
- Path jitter operation.

Procedure

1. Enter system view.
   system-view
2. Enter the view of an existing NQA operation.
   nqa entry *admin-name operation-tag*
3. Enable the saving of history records for the NQA operation.
   history-record enable
   By default, this feature is enabled only for the UDP tracert operation.
4. Set the lifetime of history records.
   history-record keep-time *keep-time*

The default setting is 120 minutes.

A record is deleted when its lifetime is reached.

5. Set the maximum number of history records that can be saved.

   history-record number *number*

   The default setting is 50.

   When the maximum number of history records is reached, the system will delete the oldest record to save a new one.

Scheduling the NQA operation on the NQA client

About this task

The NQA operation runs between the specified start time and end time (the start time plus operation duration). If the specified start time is ahead of the system time, the operation starts immediately. If both the specified start and end time are ahead of the system time, the operation does not start. To display the current system time, use the **display clock** command.

Restrictions and guidelines

You cannot enter the operation type view or the operation view of a scheduled NQA operation.

A system time adjustment does not affect started or completed NQA operations. It affects only the NQA operations that have not started.

Procedure

1. Enter system view.

   system-view

2. Specify the scheduling parameters for an NQA operation.

   nqa schedule *admin-name operation-tag* **start-time** { *hh:mm:ss* [*yyyy/mm/dd* | *mm/dd/yyyy*] | **now** } **lifetime** { *lifetime* | **forever** } [**recurring**]

Configuring NQA templates on the NQA client

Restrictions and guidelines

Some operation parameters for an NQA template can be specified by the template configuration or the feature that uses the template. When both are specified, the parameters in the template configuration take effect.

NQA template tasks at a glance

To configure NQA templates, perform the following tasks:

1. Perform at least one of the following tasks:
   - Configuring the ICMP template
   - Configuring the DNS template
   - Configuring the TCP template
   - Configuring the TCP half open template
   - Configuring the UDP template
   - Configuring the HTTP template
   - Configuring the HTTPS template

- Configuring the FTP template
- Configuring the RADIUS template
- Configuring the SSL template

2. (Optional.) Configuring optional parameters for the NQA template

Configuring the ICMP template

About this task

A feature that uses the ICMP template performs the ICMP operation to measure the reachability of a destination device. The ICMP template is supported on both IPv4 and IPv6 networks.

Procedure

1. Enter system view.

   system-view

2. Create an ICMP template and enter its view.

   nqa template icmp *name*

3. Specify the destination IP address for the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is configured.

4. Specify the source IP address for ICMP echo requests. Choose one option as needed:
   - Use the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the primary IP address of the output interface is used as the source IP address of ICMP echo requests.

     The specified source interface must be up.
   - Specify the source IPv4 address.

     source ip *ip-address*

     By default, the primary IPv4 address of the output interface is used as the source IPv4 address of ICMP echo requests.

     The specified source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.
   - Specify the source IPv6 address.

     source ipv6 *ipv6-address*

     By default, the primary IPv6 address of the output interface is used as the source IPv6 address of ICMP echo requests.

     The specified source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

5. Specify the next hop IP address for ICMP echo requests.

   IPv4:

   next-hop ip *ip-address*

   IPv6:

   next-hop ipv6 *ipv6-address*

   By default, no IP address of the next hop is configured.

To avoid probe failure, make sure the IP address belongs to a directly connected next hop.

6. Configure the probe result sending on a per-probe basis.

   reaction trigger per-probe

   By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

7. (Optional.) Set the payload size for each ICMP request.

   data-size *size*

   The default setting is 100 bytes.

8. (Optional.) Specify the payload fill string for ICMP echo requests.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the DNS template

About this task

A feature that uses the DNS template performs the DNS operation to determine the status of the server. The DNS template is supported on both IPv4 and IPv6 networks.

In DNS template view, you can specify the address expected to be returned. If the returned IP addresses include the expected address, the DNS server is valid and the operation succeeds. Otherwise, the operation fails.

Prerequisites

Create a mapping between the domain name and an address before you perform the DNS operation. For information about configuring the DNS server, see documents about the DNS server configuration.

Procedure

1. Enter system view.

   system-view

2. Create a DNS template and enter DNS template view.

   nqa template dns *name*

3. Specify the destination IP address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. Specify the destination port number for the probe packets.

   destination port *port-number*

   By default, the destination port number is 53.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

By default, the source IPv4 address of the probe packets is the primary IPv4 address of their output interface.

The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the source IPv6 address of the probe packets is the primary IPv6 address of their output interface.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the source port number for the probe packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

7. Specify the domain name to be translated.

   resolve-target *domain-name*

   By default, no domain name is specified.

8. Specify the domain name resolution type.

   resolve-type { **A** | **AAAA** }

   By default, the type is type A.

   A type A query resolves a domain name to a mapped IPv4 address, and a type AAAA query to a mapped IPv6 address.

9. (Optional.) Specify the IP address that is expected to be returned.

   IPv4:

   expect ip *ip-address*

   IPv6:

   expect ipv6 *ipv6-address*

   By default, no expected IP address is specified.

Configuring the TCP template

About this task

A feature that uses the TCP template performs the TCP operation to test whether the NQA client can establish a TCP connection to a specific port on the server.

In TCP template view, you can specify the expected data to be returned. If you do not specify the expected data, the TCP operation tests only whether the client can establish a TCP connection to the server.

The TCP operation requires both the NQA server and the NQA client. Before you perform a TCP operation, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "Configuring the NQA server."

Procedure

1. Enter system view.

   system-view

2. Create a TCP template and enter its view.

nqa template tcp *name*

3. Specify the destination IP address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. (Optional.) Specify the payload fill string for the probe packets.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

7. (Optional.) Configure the expected data.

   expect data *expression* [**offset** *number*]

   By default, no expected data is configured.

   The NQA client performs expect data check only when you configure both the **data-fill** and **expect-data** commands.

Configuring the TCP half open template

About this task

A feature that uses the TCP half open template performs the TCP half open operation to test whether the TCP service is available on the server. The TCP half open operation is used when the feature cannot get a response from the TCP server through an existing TCP connection.

In the TCP half open operation, the NQA client sends a TCP ACK packet to the server. If the client receives an RST packet, it considers that the TCP service is available on the server.

Procedure

1. Enter system view.

   system-view

2. Create a TCP half open template and enter its view.

   nqa template tcphalfopen *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

4. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

5. Specify the next hop IP address for the probe packets.

   IPv4:

   next-hop ip *ip-address*

   IPv6:

   next-hop ipv6 *ipv6-address*

   By default, the IP address of the next hop is configured.

   To avoid probe failure, make sure the IP address belongs to a directly connected next hop.

6. Configure the probe result sending on a per-probe basis.

   reaction trigger per-probe

   By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

Configuring the UDP template

About this task

A feature that uses the UDP template performs the UDP operation to test the following items:

- Reachability of a specific port on the NQA server.
- Availability of the requested service on the NQA server.

In UDP template view, you can specify the expected data to be returned. If you do not specify the expected data, the UDP operation tests only whether the client can receive the response packet from the server.

The UDP operation requires both the NQA server and the NQA client. Before you perform a UDP operation, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "Configuring the NQA server."

Procedure

1. Enter system view.

   system-view

2. Create a UDP template and enter its view.

   nqa template udp *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the payload fill string for the probe packets.
   data-fill *string*
   The default payload fill string is the hexadecimal string 00010203040506070809.
7. (Optional.) Set the payload size for the probe packets.
   data-size *size*
   The default setting is 100 bytes.
8. (Optional.) Configure the expected data.
   expect data *expression* [**offset** *number*]
   By default, no expected data is configured.
   Expected data check is performed only when both the **data-fill** command and the **expect data** command are configured.

Configuring the HTTP template

About this task

A feature that uses the HTTP template performs the HTTP operation to measure the time it takes the NQA client to obtain data from an HTTP server.

The expected data is checked only when the data is configured and the HTTP response contains the Content-Length field in the HTTP header.

The status code of the HTTP packet is a three-digit field in decimal notation, and it includes the status information for the HTTP server. The first digit defines the class of response.

Prerequisites

Before you perform the HTTP operation, you must configure the HTTP server.

Procedure

1. Enter system view.
   system-view
2. Create an HTTP template and enter its view.
   nqa template http *name*
3. Specify the destination URL for the HTTP template.
   url *url*
   By default, no destination URL is specified for an HTTP template.
   Enter the URL in one of the following formats:
   - http://*host*/*resource*
   - http://*host*:*port*/*resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, http://[2001::1]/test.
4. Specify an HTTP login username.
   username *username*
   By default, no HTTP login username is specified.
5. Specify an HTTP login password.
   password { **cipher** | **simple** } *string*
   By default, no HTTP login password is specified.
6. Specify the HTTP version.
   version { **v1.0** | **v1.1** }

By default, HTTP 1.0 is used.

7. Specify the HTTP operation type.

   operation { **get** | **post** | **raw** }

   By default, the HTTP operation type is **get**.

   If you set the operation type to raw, the client pads the content configured in raw request view to the HTTP request to send to the HTTP server.

8. Configure the content of the HTTP raw request.

   a. Enter raw request view.

      raw-request

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

      By default, no request content is configured.

      To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

   c. Return to HTTP template view.

      quit

      The system automatically saves the configuration in raw request view before it returns to HTTP template view.

   This step is required only when the operation type is set to **raw**.

9. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

10. (Optional.) Configure the expected status codes.

    expect status *status-list*

    By default, no expected status code is configured.

11. (Optional.) Configure the expected data.

    expect data *expression* [**offset** *number*]

    By default, no expected data is configured.

Configuring the HTTPS template

About this task

A feature that uses the HTTPS template performs the HTTPS operation to measure the time it takes for the NQA client to obtain data from an HTTPS server.

The expected data is checked only when the expected data is configured and the HTTPS response contains the Content-Length field in the HTTPS header.

The status code of the HTTPS packet is a three-digit field in decimal notation, and it includes the status information for the HTTPS server. The first digit defines the class of response.

Prerequisites

Before you perform the HTTPS operation, configure the HTTPS server and the SSL client policy for the SSL client. For information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create an HTTPS template and enter its view.

   nqa template https *name*

3. Specify the destination URL for the HTTPS template.

   url *url*

   By default, no destination URL is specified for an HTTPS template.

   Enter the URL in one of the following formats:

   - https://*host*/*resource*
   - https://*host*:*port*/*resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, https://[2001::1]/test.

4. Specify an HTTPS login username.

   username *username*

   By default, no HTTPS login username is specified.

5. Specify an HTTPS login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTPS login password is specified.

6. Specify an SSL client policy.

   ssl-client-policy *policy-name*

   By default, no SSL client policy is specified.

7. Specify the HTTPS version.

   version { **v1.0** | **v1.1** }

   By default, HTTPS 1.0 is used.

8. Specify the HTTPS operation type.

   operation { **get** | **post** | **raw** }

   By default, the HTTPS operation type is **get**.

   If you set the operation type to raw, the client pads the content configured in raw request view to the HTTPS request to send to the HTTPS server.

9. Configure the content of the HTTPS raw request.

   a. Enter raw request view.

      raw-request

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

By default, no request content is configured.

To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

c. Return to HTTPS template view.

quit

The system automatically saves the configuration in raw request view before it returns to HTTPS template view.

This step is required only when the operation type is set to **raw**.

10. Specify the source IP address for the probe packets.

IPv4:

source ip *ip-address*

By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

11. (Optional.) Configure the expected data.

expect data *expression* [**offset** *number*]

By default, no expected data is configured.

12. (Optional.) Configure the expected status codes.

expect status *status-list*

By default, no expected status code is configured.

Configuring the FTP template

About this task

A feature that uses the FTP template performs the FTP operation. The operation measures the time it takes the NQA client to transfer a file to or download a file from an FTP server.

Configure the username and password for the FTP client to log in to the FTP server before you perform an FTP operation. For information about configuring the FTP server, see *Fundamentals Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Create an FTP template and enter its view.

nqa template ftp *name*

3. Specify an FTP login username.

username *username*

By default, no FTP login username is specified.

4. Specify an FTP login password.

password { **cipher** | **simple** } *sting*

By default, no FTP login password is specified.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Set the data transmission mode.

   mode { **active** | **passive** }

   The default mode is **active**.

7. Specify the FTP operation type.

   operation { **get** | **put** }

   By default, the FTP operation type is **get**, which means obtaining files from the FTP server.

8. Specify the destination URL for the FTP template.

   url *url*

   By default, no destination URL is specified for an FTP template.

   Enter the URL in one of the following formats:

   - ftp://*host*/*filename*.
   - ftp://*host*:*port*/*filename*.

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, ftp://[2001::1]/test.

   When you perform the **get** operation, the file name is required.

   When you perform the **put** operation, the *filename* argument does not take effect, even if it is specified. The file name for the **put** operation is determined by using the **filename** command.

9. Specify the name of a file to be transferred.

   filename *filename*

   By default, no file is specified.

   This task is required only for the **put** operation.

   The configuration does not take effect for the **get** operation.

Configuring the RADIUS template

About this task

A feature that uses the RADIUS template performs the RADIUS authentication operation to check the availability of the authentication service on the RADIUS server.

The RADIUS authentication operation workflow is as follows:

1. The NQA client sends an authentication request (Access-Request) to the RADIUS server. The request includes the username and the password. The password is encrypted by using the MD5 algorithm and the shared key.
2. The RADIUS server authenticates the username and password.
   - If the authentication succeeds, the server sends an Access-Accept packet to the NQA client.
   - If the authentication fails, the server sends an Access-Reject packet to the NQA client.
3. The NQA client determines the availability of the authentication service on the RADIUS server based on the response packet it received:
   - If an Access-Accept packet is received, the authentication service is available on the RADIUS server.
   - If an Access-Reject packet is received, the authentication service is not available on the RADIUS server.

Prerequisites

Before you configure the RADIUS template, specify a username, password, and shared key on the RADIUS server. For more information about configuring the RADIUS server, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Create a RADIUS template and enter its view.

   nqa template radius *name*
3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.
4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, the destination port number is 1812.
5. Specify a username.

   username *username*

   By default, no username is specified.
6. Specify a password.

   password { **cipher** | **simple** } *string*

   By default, no password is specified.
7. Specify a shared key for secure RADIUS authentication.

   key { **cipher** | **simple** } *string*

   By default, no shared key is specified for RADIUS authentication.
8. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the SSL template

About this task

A feature that uses the SSL template performs the SSL operation to measure the time required to establish an SSL connection to an SSL server.

Prerequisites

Before you configure the SSL template, you must configure the SSL client policy. For information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create an SSL template and enter its view.

   nqa template ssl *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, the destination port number is not specified.

5. Specify an SSL client policy.

   ssl-client-policy *policy-name*

   By default, no SSL client policy is specified.

6. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring optional parameters for the NQA template

Restrictions and guidelines

Unless otherwise specified, the following optional parameters apply to all types of NQA templates.

The parameter settings take effect only on the current NQA template.

Procedure

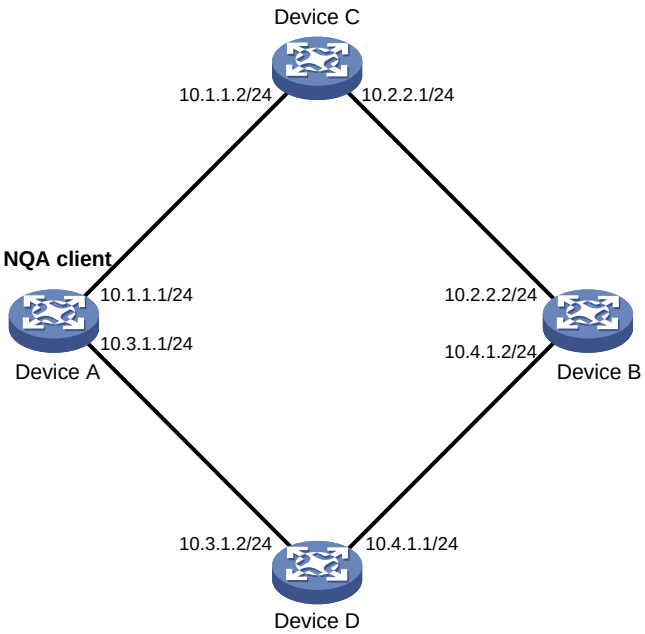
1. Enter system view.
   system-view
2. Enter the view of an existing NQA template.
   nqa template { **dns** | **ftp** | **http** | **https** | **icmp** | **radius** | **ssl** | **tcp** | **tcphalfopen** | **udp** } *name*
3. Configure a description.
   description *text*
   By default, no description is configured.
4. Set the interval at which the NQA operation repeats.
   frequency *interval*
   The default setting is 5000 milliseconds.
   If the operation is not completed when the interval expires, the next operation does not start.
5. Set the probe timeout time.
   probe timeout *timeout*
   The default setting is 3000 milliseconds.
6. Set the TTL for the probe packets.
   ttl *value*
   The default setting is 20.
   This command is not available for the ARP template.
7. Set the ToS value in the IP header of the probe packets.
   tos *value*
   The default setting is 0.
   This command is not available for the ARP template.
8. Specify the VPN instance where the operation is performed.
   vpn-instance *vpn-instance-name*
   By default, the operation is performed on the public network.
9. Set the number of consecutive successful probes to determine a successful operation event.
   reaction trigger probe-pass *count*
   The default setting is 3.
   If the number of consecutive successful probes for an NQA operation is reached, the NQA client notifies the feature that uses the template of the successful operation event.
10. Set the number of consecutive probe failures to determine an operation failure.
    reaction trigger probe-fail *count*
    The default setting is 3.

If the number of consecutive probe failures for an NQA operation is reached, the NQA client notifies the feature that uses the NQA template of the operation failure.

Display and maintenance commands for NQA

Execute **display** commands in any view.

Task	Command
Display history records of NQA operations.	**display nqa history** [*admin-name operation-tag*]
Display the current monitoring results of reaction entries.	**display nqa reaction counters** [*admin-name operation-tag* [*item-number*]]
Display the most recent result of the NQA operation.	**display nqa result** [*admin-name operation-tag*]
Display NQA server status.	**display nqa server status**
Display NQA statistics.	**display nqa statistics** [*admin-name operation-tag*]



NQA configuration examples

Example: Configuring the ICMP echo operation

Network configuration

As shown in Figure 2, configure an ICMP echo operation on the NQA client (Device A) to test the round-trip time to Device B. The next hop of Device A is Device C.

Figure 2 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 2. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an ICMP echo operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type icmp-echo
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqa-admin-test1-icmp-echo] destination ip 10.2.2.2
```

Specify 10.1.1.2 as the next hop. The ICMP echo requests are sent through Device C to Device B.

```
[DeviceA-nqa-admin-test1-icmp-echo] next-hop ip 10.1.1.2
```

Configure the ICMP echo operation to perform 10 probes.

```
[DeviceA-nqa-admin-test1-icmp-echo] probe count 10
```

Set the probe timeout time to 500 milliseconds for the ICMP echo operation.

```
[DeviceA-nqa-admin-test1-icmp-echo] probe timeout 500
```

Configure the ICMP echo operation to repeat every 5000 milliseconds.

```
[DeviceA-nqa-admin-test1-icmp-echo] frequency 5000
```

Enable saving history records.

```
[DeviceA-nqa-admin-test1-icmp-echo] history-record enable
```

Set the maximum number of history records to 10.

```
[DeviceA-nqa-admin-test1-icmp-echo] history-record number 10
[DeviceA-nqa-admin-test1-icmp-echo] quit
```

Start the ICMP echo operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the ICMP echo operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the ICMP echo operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 10             Receive response times: 10
    Min/Max/Average round trip time: 2/5/3
    Square-Sum of round trip time: 96
    Last succeeded probe time: 2019-08-23 15:00:01.2
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the ICMP echo operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test) history records:
  Index      Response     Status           Time
  370        3            Succeeded        2019-08-23 15:00:01.2
```

```
369         3           Succeeded       2019-08-23 15:00:01.2
368         3           Succeeded       2019-08-23 15:00:01.2
367         5           Succeeded       2019-08-23 15:00:01.2
366         3           Succeeded       2019-08-23 15:00:01.2
365         3           Succeeded       2019-08-23 15:00:01.2
364         3           Succeeded       2019-08-23 15:00:01.1
363         2           Succeeded       2019-08-23 15:00:01.1
362         3           Succeeded       2019-08-23 15:00:01.1
361         2           Succeeded       2019-08-23 15:00:01.1
```

The output shows that the packets sent by Device A can reach Device B through Device C. No packet loss occurs during the operation. The minimum, maximum, and average round-trip times are 2, 5, and 3 milliseconds, respectively.

Example: Configuring the ICMP jitter operation

Network configuration

As shown in Figure 3, configure an ICMP jitter operation to test the jitter between Device A and Device B.

Figure 3 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 3. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device A:

   # Create an ICMP jitter operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type icmp-jitter
   ```

   # Specify 10.2.2.2 as the destination address for the operation.

   ```
   [DeviceA-nqa-admin-test1-icmp-jitter] destination ip 10.2.2.2
   ```

   # Configure the operation to repeat every 1000 milliseconds.

   ```
   [DeviceA-nqa-admin-test1-icmp-jitter] frequency 1000
   [DeviceA-nqa-admin-test1-icmp-jitter] quit
   ```

   # Start the ICMP jitter operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the ICMP jitter operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the ICMP jitter operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
```

```
    Send operation times: 10             Receive response times: 10
    Min/Max/Average round trip time: 1/2/1
    Square-Sum of round trip time: 13
    Last packet received time: 2019-03-09 17:40:29.8
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
    Packets out of sequence: 0
    Packets arrived late: 0
  ICMP-jitter results:
   RTT number: 10
    Min positive SD: 0                   Min positive DS: 0
    Max positive SD: 0                   Max positive DS: 0
    Positive SD number: 0                Positive DS number: 0
    Positive SD sum: 0                   Positive DS sum: 0

Example: Configuring the DHCP operation

Network configuration

As shown in Figure 4, configure a DHCP operation to test the time required for Switch A to obtain an IP address from the DHCP server (Switch B).

Figure 4 Network diagram

Procedure

Create a DHCP operation.

```
<SwitchA> system-view
[SwitchA] nqa entry admin test1
[SwitchA-nqa-admin-test1] type dhcp
```

Specify the DHCP server address (10.1.1.2) as the destination address.

```
[SwitchA-nqa-admin-test1-dhcp] destination ip 10.1.1.2
```

Enable the saving of history records.

```
[SwitchA-nqa-admin-test1-dhcp] history-record enable
[SwitchA-nqa-admin-test1-dhcp] quit
```

Start the DHCP operation.

```
[SwitchA] nqa schedule admin test1 start-time now lifetime forever
```

After the DHCP operation runs for a period of time, stop the operation.

```
[SwitchA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the DHCP operation.

```
[SwitchA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 512/512/512
    Square-Sum of round trip time: 262144
    Last succeeded probe time: 2019-11-22 09:56:03.2
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DHCP operation.

```
[SwitchA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          512          Succeeded        2019-11-22 09:56:03.2
```

The output shows that it took Switch A 512 milliseconds to obtain an IP address from the DHCP server.

Example: Configuring the DNS operation

Network configuration

As shown in Figure 5, configure a DNS operation to test whether Device A can perform address resolution through the DNS server and test the resolution time.

Figure 5 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 5. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create a DNS operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type dns
```

Specify the IP address of the DNS server (10.2.2.2) as the destination address.

```
[DeviceA-nqa-admin-test1-dns] destination ip 10.2.2.2
```

Specify **host.com** as the domain name to be translated.

```
[DeviceA-nqa-admin-test1-dns] resolve-target host.com
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-dns] history-record enable
[DeviceA-nqa-admin-test1-dns] quit
```

Start the DNS operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the DNS operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the DNS operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 62/62/62
    Square-Sum of round trip time: 3844
    Last succeeded probe time: 2019-11-10 10:49:37.3
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DNS operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test) history records:
  Index      Response     Status           Time
  1          62           Succeeded        2019-11-10 10:49:37.3
```

The output shows that it took Device A 62 milliseconds to translate domain name **host.com** into an IP address.

Example: Configuring the FTP operation

Network configuration

As shown in Figure 6, configure an FTP operation to test the time required for Device A to upload a file to the FTP server. The login username and password are **admin** and **systemtest**, respectively. The file to be transferred to the FTP server is **config.txt**.

Figure 6 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 6. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an FTP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type ftp
```

Specify the URL of the FTP server.

```
[DeviceA-nqa-admin-test-ftp] url ftp://10.2.2.2
```

Specify 10.1.1.1 as the source IP address.

```
[DeviceA-nqa-admin-test1-ftp] source ip 10.1.1.1
```

Configure the device to upload file **config.txt** to the FTP server.

```
[DeviceA-nqa-admin-test1-ftp] operation put
[DeviceA-nqa-admin-test1-ftp] filename config.txt
```

Set the username to **admin** for the FTP operation.

```
[DeviceA-nqa-admin-test1-ftp] username admin
```

Set the password to **systemtest** for the FTP operation.

```
[DeviceA-nqa-admin-test1-ftp] password simple systemtest
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-ftp] history-record enable
[DeviceA-nqa-admin-test1-ftp] quit
```

Start the FTP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the FTP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the FTP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 173/173/173
    Square-Sum of round trip time: 29929
    Last succeeded probe time: 2019-11-22 10:07:28.6
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the FTP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          173          Succeeded        2019-11-22 10:07:28.6
```

The output shows that it took Device A 173 milliseconds to upload a file to the FTP server.

Example: Configuring the HTTP operation

Network configuration

As shown in Figure 7, configure an HTTP operation on the NQA client to test the time required to obtain data from the HTTP server.

Figure 7 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 7. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an HTTP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type http
```

Specify the URL of the HTTP server.

```
[DeviceA-nqa-admin-test1-http] url http://10.2.2.2/index.htm
```

Configure the HTTP operation to get data from the HTTP server.

```
[DeviceA-nqa-admin-test1-http] operation get
```

Configure the operation to use HTTP version 1.0.

```
[DeviceA-nqa-admin-test1-http] version v1.0
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-http] history-record enable
[DeviceA-nqa-admin-test1-http] quit
```

Start the HTTP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the HTTP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the HTTP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 64/64/64
    Square-Sum of round trip time: 4096
    Last succeeded probe time: 2019-11-22 10:12:47.9
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
```

```
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the HTTP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          64           Succeeded        2019-11-22 10:12:47.9
```

The output shows that it took Device A 64 milliseconds to obtain data from the HTTP server.

Example: Configuring the UDP jitter operation

Network configuration

As shown in Figure 8, configure a UDP jitter operation to test the jitter, delay, and round-trip time between Device A and Device B.

Figure 8 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 8. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a UDP jitter operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-jitter
   ```

   # Specify 10.2.2.2 as the destination address of the operation.

   ```
   [DeviceA-nqa-admin-test1-udp-jitter] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqa-admin-test1-udp-jitter] destination port 9000
   ```

   # Configure the operation to repeat every 1000 milliseconds.

   ```
   [DeviceA-nqa-admin-test1-udp-jitter] frequency 1000
   [DeviceA-nqa-admin-test1-udp-jitter] quit
   ```

   # Start the UDP jitter operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the UDP jitter operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the UDP jitter operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 10             Receive response times: 10
    Min/Max/Average round trip time: 15/32/17
    Square-Sum of round trip time: 3235

Example: Configuring the SNMP operation

Network configuration

As shown in Figure 9, configure an SNMP operation to test the time the NQA client uses to get a response from the SNMP agent.

Figure 9 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 9. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure the SNMP agent (Device B):

   # Set the SNMP version to **all**.

```
<DeviceB> system-view
[DeviceB] snmp-agent sys-info version all
```

Set the read community to **public**.

```
[DeviceB] snmp-agent community read public
```

Set the write community to **private**.

```
[DeviceB] snmp-agent community write private
```

4. Configure Device A:

Create an SNMP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type snmp
```

Specify 10.2.2.2 as the destination IP address of the SNMP operation.

```
[DeviceA-nqa-admin-test1-snmp] destination ip 10.2.2.2
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-snmp] history-record enable
[DeviceA-nqa-admin-test1-snmp] quit
```

Start the SNMP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the SNMP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the SNMP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 50/50/50
    Square-Sum of round trip time: 2500
    Last succeeded probe time: 2019-11-22 10:24:41.1
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the SNMP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          50           Succeeded        2019-11-22 10:24:41.1
```

The output shows that it took Device A 50 milliseconds to receive a response from the SNMP agent.

Example: Configuring the TCP operation

Network configuration

As shown in Figure 10, configure a TCP operation to test the time required for Device A to establish a TCP connection with Device B.

Figure 10 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 10. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to TCP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server tcp-connect 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a TCP operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type tcp
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-tcp] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqa-admin-test1-tcp] destination port 9000
   ```

   # Enable the saving of history records.

   ```
   [DeviceA-nqa-admin-test1-tcp] history-record enable
   [DeviceA-nqa-admin-test1-tcp] quit
   ```

   # Start the TCP operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the TCP operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the TCP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 13/13/13
    Square-Sum of round trip time: 169
    Last succeeded probe time: 2019-11-22 10:27:25.1
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
```

```
    Failures due to other errors: 0
```

Display the history records of the TCP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          13           Succeeded        2019-11-22 10:27:25.1
```

The output shows that it took Device A 13 milliseconds to establish a TCP connection to port 9000 on the NQA server.

Example: Configuring the UDP echo operation

Network configuration

As shown in Figure 11, configure a UDP echo operation on the NQA client to test the round-trip time to Device B. The destination port number is 8000.

Figure 11 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 11. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 8000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 8000
   ```

4. Configure Device A:

   # Create a UDP echo operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-echo
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] destination ip 10.2.2.2
   ```

   # Set the destination port number to 8000.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] destination port 8000
   ```

   # Enable the saving of history records.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] history-record enable
   [DeviceA-nqa-admin-test1-udp-echo] quit
   ```

   # Start the UDP echo operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the UDP echo operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the UDP echo operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 25/25/25
    Square-Sum of round trip time: 625
    Last succeeded probe time: 2019-11-22 10:36:17.9
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the UDP echo operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          25           Succeeded        2019-11-22 10:36:17.9
```

The output shows that the round-trip time between Device A and port 8000 on Device B is 25 milliseconds.

Example: Configuring the UDP tracert operation

Network configuration

As shown in Figure 12, configure a UDP tracert operation to determine the routing path from Device A to Device B.

Figure 12 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 12. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Execute the **ip ttl-expires enable** command on the intermediate devices and execute the **ip unreachables enable** command on Device B.
4. Configure Device A:

   # Create a UDP tracert operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-tracert
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] destination ip 10.2.2.2
   ```

   # Set the destination port number to 33434.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] destination port 33434
   ```

Configure Device A to perform three probes to each hop.

```
[DeviceA-nqa-admin-test1-udp-tracert] probe count 3
```

Set the probe timeout time to 500 milliseconds.

```
[DeviceA-nqa-admin-test1-udp-tracert] probe timeout 500
```

Configure the UDP tracert operation to repeat every 5000 milliseconds.

```
[DeviceA-nqa-admin-test1-udp-tracert] frequency 5000
```

Specify GigabitEthernet 1/0/1 as the output interface for UDP packets.

```
[DeviceA-nqa-admin-test1-udp-tracert] out interface gigabitethernet 1/0/1
```

Enable the no-fragmentation feature.

```
[DeviceA-nqa-admin-test1-udp-tracert] no-fragment enable
```

Set the maximum number of consecutive probe failures to 6.

```
[DeviceA-nqa-admin-test1-udp-tracert] max-failure 6
```

Set the TTL value to 1 for UDP packets in the start round of the UDP tracert operation.

```
[DeviceA-nqa-admin-test1-udp-tracert] init-ttl 1
```

Start the UDP tracert operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the UDP tracert operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the UDP tracert operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 6              Receive response times: 6
    Min/Max/Average round trip time: 1/1/1
    Square-Sum of round trip time: 1
    Last succeeded probe time: 2019-09-09 14:46:06.2

Example: Configuring the voice operation

Network configuration

As shown in Figure 13, configure a voice operation to test jitters, delay, MOS, and ICPIF between Device A and Device B.

Figure 13 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 13. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a voice operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type voice
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-voice] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqa-admin-test1-voice] destination port 9000
   [DeviceA-nqa-admin-test1-voice] quit
   ```

   # Start the voice operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the voice operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

```

Example: Configuring the DLSw operation

Network configuration

As shown in Figure 14, configure a DLSw operation to test the response time of the DLSw device.

Figure 14 Network diagram

Configuring Device A

Assign IP addresses to interfaces, as shown in Figure 14. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create a DLSw operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type dlsw
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqa-admin-test1-dlsw] destination ip 10.2.2.2
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-dlsw] history-record enable
[DeviceA-nqa-admin-test1-dlsw] quit
```

Start the DLSw operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the DLSw operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Configuring Device B

Assign IP addresses to interfaces. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can communicate with each other. (Details not shown.)

Enable the NQA server.

```
<DeviceB> system-view
[DeviceB] nqa server enable
```

Configure a listening service to listen to TCP port 2065 on IP address 10.2.2.2. (For the DLSw operation, the port number for the TCP listening service must be 2065.)

```
[DeviceB] nqa server tcp-connect 10.2.2.2 2065
```

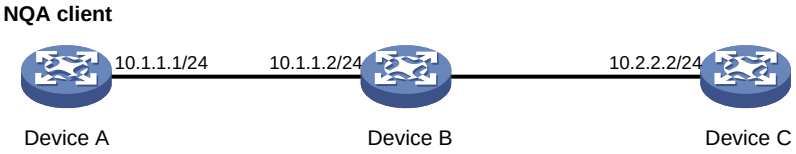
Verifying the configuration

Display the most recent result of the DLSw operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 19/19/19
    Square-Sum of round trip time: 361
    Last succeeded probe time: 2019-11-22 10:40:27.7
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DLSw operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          19           Succeeded        2019-11-22 10:40:27.7
```



The output shows that the response time of the DLSw device is 19 milliseconds.

Example: Configuring the path jitter operation

Network configuration

As shown in Figure 15, configure a path jitter operation to test the round trip time and jitters from Device A to Device B and Device C.

Figure 15 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 15. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Execute the **ip ttl-expires enable** command on Device B and execute the **ip unreachables enable** command on Device C.

Create a path jitter operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type path-jitter
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqa-admin-test1-path-jitter] destination ip 10.2.2.2
```

Configure the path jitter operation to repeat every 10000 milliseconds.

```
[DeviceA-nqa-admin-test1-path-jitter] frequency 10000
[DeviceA-nqa-admin-test1-path-jitter] quit
```

Start the path jitter operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the path jitter operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the path jitter operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
  Hop IP 10.1.1.2
    Basic Results

```

Example: Configuring NQA collaboration

Network configuration

As shown in Figure 16, configure a static route to Switch C with Switch B as the next hop on Switch A. Associate the static route, a track entry, and an ICMP echo operation to monitor the state of the static route.

Figure 16 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 16. (Details not shown.)
2. On Switch A, configure a static route, and associate the static route with track entry 1.

```
<SwitchA> system-view
```

```
[SwitchA] ip route-static 10.1.1.2 24 10.2.1.1 track 1
```

3. On Switch A, configure an ICMP echo operation:

Create an NQA operation with administrator name **admin** and operation tag **test1**.

```
[SwitchA] nqa entry admin test1
```

Configure the NQA operation type as ICMP echo.

```
[SwitchA-nqa-admin-test1] type icmp-echo
```

Specify 10.2.1.1 as the destination IP address.

```
[SwitchA-nqa-admin-test1-icmp-echo] destination ip 10.2.1.1
```

Configure the operation to repeat every 100 milliseconds.

```
[SwitchA-nqa-admin-test1-icmp-echo] frequency 100
```

Create reaction entry 1. If the number of consecutive probe failures reaches 5, collaboration is triggered.

```
[SwitchA-nqa-admin-test1-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchA-nqa-admin-test1-icmp-echo] quit
```

Start the ICMP operation.

```
[SwitchA] nqa schedule admin test1 start-time now lifetime forever
```

4. On Switch A, create track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchA] track 1 nqa entry admin test1 reaction 1
```

Verifying the configuration

Display information about all the track entries on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 0 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test1
    Reaction: 1
```

Display brief information about active routes in the routing table on Switch A.

```
[SwitchA] display ip routing-table

Destinations : 13        Routes : 13

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
10.1.1.0/24         Static 60   0            10.2.1.1        Vlan3
10.2.1.0/24         Direct 0    0            10.2.1.2        Vlan3
10.2.1.0/32         Direct 0    0            10.2.1.2        Vlan3
10.2.1.2/32         Direct 0    0            127.0.0.1       InLoop0
10.2.1.255/32       Direct 0    0            10.2.1.2        Vlan3
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
224.0.0.0/4         Direct 0    0            0.0.0.0         NULL0
224.0.0.0/24        Direct 0    0            0.0.0.0         NULL0
```

```
255.255.255.255/32  Direct 0    0           127.0.0.1       InLoop0
```

The output shows that the static route with the next hop 10.2.1.1 is active, and the status of the track entry is positive.

Remove the IP address of VLAN-interface 3 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] undo ip address
```

Display information about all the track entries on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 0 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test1
    Reaction: 1
```

Display brief information about active routes in the routing table on Switch A.

```
[SwitchA] display ip routing-table

Destinations : 12        Routes : 12

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0           127.0.0.1       InLoop0
10.2.1.0/24         Direct 0    0           10.2.1.2        Vlan3
10.2.1.0/32         Direct 0    0           10.2.1.2        Vlan3

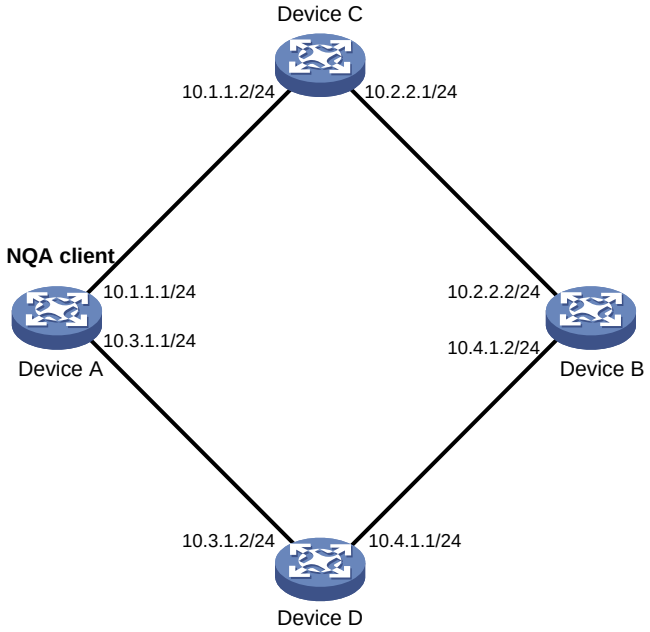
127.0.0.1/32        Direct 0    0           127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0           127.0.0.1       InLoop0
224.0.0.0/4         Direct 0    0           0.0.0.0         NULL0
224.0.0.0/24        Direct 0    0           0.0.0.0         NULL0
255.255.255.255/32  Direct 0    0           127.0.0.1       InLoop0
```



The output shows that the static route does not exist, and the status of the track entry is negative.

Example: Configuring the ICMP template

Network configuration

As shown in Figure 17, configure an ICMP template for a feature to perform the ICMP echo operation from Device A to Device B.

Figure 17 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 17. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create ICMP template **icmp**.

```
<DeviceA> system-view
[DeviceA] nqa template icmp icmp
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqatplt-icmp-icmp] destination ip 10.2.2.2
```

Set the probe timeout time to 500 milliseconds for the ICMP echo operation.

```
[DeviceA-nqatplt-icmp-icmp] probe timeout 500
```

Configure the ICMP echo operation to repeat every 3000 milliseconds.

```
[DeviceA-nqatplt-icmp-icmp] frequency 3000
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-icmp-icmp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-icmp-icmp] reaction trigger probe-fail 2
```

Example: Configuring the DNS template

Network configuration

As shown in Figure 18, configure a DNS template for a feature to perform the DNS operation. The operation tests whether Device A can perform the address resolution through the DNS server.

Figure 18 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 18. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create DNS template **dns**.

```
<DeviceA> system-view
[DeviceA] nqa template dns dns
```

Specify the IP address of the DNS server (10.2.2.2) as the destination IP address.

```
[DeviceA-nqatplt-dns-dns] destination ip 10.2.2.2
```

Specify **host.com** as the domain name to be translated.

```
[DeviceA-nqatplt-dns-dns] resolve-target host.com
```

Set the domain name resolution type to type A.

```
[DeviceA-nqatplt-dns-dns] resolve-type A
```

Specify 3.3.3.3 as the expected IP address.

```
[DeviceA-nqatplt-dns-dns] expect ip 3.3.3.3
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-dns-dns] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-dns-dns] reaction trigger probe-fail 2
```

Example: Configuring the TCP template

Network configuration

As shown in Figure 19, configure a TCP template for a feature to perform the TCP operation. The operation tests whether Device A can establish a TCP connection to Device B.

Figure 19 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 19. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

```
<DeviceB> system-view
[DeviceB] nqa server enable
```

Configure a listening service to listen to TCP port 9000 on IP address 10.2.2.2.

```
[DeviceB] nqa server tcp-connect 10.2.2.2 9000
```

4. Configure Device A:

Create TCP template **tcp**.

```
<DeviceA> system-view
[DeviceA] nqa template tcp tcp
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqatplt-tcp-tcp] destination ip 10.2.2.2
```

Set the destination port number to 9000.

```
[DeviceA-nqatplt-tcp-tcp] destination port 9000
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-tcp-tcp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-tcp-tcp] reaction trigger probe-fail 2
```

Example: Configuring the TCP half open template

Network configuration

As shown in Figure 20, configure a TCP half open template for a feature to test whether Device B can provide the TCP service for Device A.

Figure 20 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 20. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device A:

Create TCP half open template **test**.

```
<DeviceA> system-view
[DeviceA] nqa template tcphalfopen test
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqatplt-tcphalfopen-test] destination ip 10.2.2.2
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-tcphalfopen-test] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-tcphalfopen-test] reaction trigger probe-fail 2
```

Example: Configuring the UDP template

Network configuration

As shown in Figure 21, configure a UDP template for a feature to perform the UDP operation. The operation tests whether Device A can receive a response from Device B.

Figure 21 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 21. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create UDP template **udp**.

   ```
   <DeviceA> system-view
   [DeviceA] nqa template udp udp
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqatplt-udp-udp] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqatplt-udp-udp] destination port 9000
   ```

   # Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

   ```
   [DeviceA-nqatplt-udp-udp] reaction trigger probe-pass 2
   ```

   # Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

   ```
   [DeviceA-nqatplt-udp-udp] reaction trigger probe-fail 2
   ```

Example: Configuring the HTTP template

Network configuration

As shown in Figure 22, configure an HTTP template for a feature to perform the HTTP operation. The operation tests whether the NQA client can get data from the HTTP server.

Figure 22 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 22. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create HTTP template **http**.

```
<DeviceA> system-view
[DeviceA] nqa template http http
```

Specify **http://10.2.2.2/index.htm** as the URL of the HTTP server.

```
[DeviceA-nqatplt-http-http] url http://10.2.2.2/index.htm
```

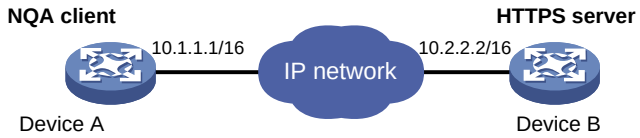
Set the HTTP operation type to **get**.

```
[DeviceA-nqatplt-http-http] operation get
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-http-http] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.



```
[DeviceA-nqatplt-http-http] reaction trigger probe-fail 2
```

Example: Configuring the HTTPS template

Network configuration

As shown in Figure 23, configure an HTTPS template for a feature to test whether the NQA client can get data from the HTTPS server (Device B).

Figure 23 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 23. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure an SSL client policy named **abc** on Device A, and make sure Device A can use the policy to connect to the HTTPS server. (Details not shown.)

Create HTTPS template **test**.

```
<DeviceA> system-view
[DeviceA] nqa template https https
```

Specify **http://10.2.2.2/index.htm** as the URL of the HTTPS server.

```
[DeviceA-nqatplt-https-https] url https://10.2.2.2/index.htm
```

Specify SSL client policy **abc** for the HTTPS template.

```
[DeviceA-nqatplt-https- https] ssl-client-policy abc
```

Set the HTTPS operation type to **get** (the default HTTPS operation type).

```
[DeviceA-nqatplt-https-https] operation get
```

Set the HTTPS version to 1.0 (the default HTTPS version).

```
 [DeviceA-nqatplt-https-https] version v1.0
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-https-https] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-https-https] reaction trigger probe-fail 2
```

Example: Configuring the FTP template

Network configuration

As shown in Figure 24, configure an FTP template for a feature to perform the FTP operation. The operation tests whether Device A can upload a file to the FTP server. The login username and password are **admin** and **systemtest**, respectively. The file to be transferred to the FTP server is **config.txt**.

Figure 24 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 24. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create FTP template **ftp**.

```
<DeviceA> system-view
[DeviceA] nqa template ftp ftp
```

Specify the URL of the FTP server.

```
[DeviceA-nqatplt-ftp-ftp] url ftp://10.2.2.2
```

Specify 10.1.1.1 as the source IP address.

```
[DeviceA-nqatplt-ftp-ftp] source ip 10.1.1.1
```

Configure the device to upload file **config.txt** to the FTP server.

```
[DeviceA-nqatplt-ftp-ftp] operation put
[DeviceA-nqatplt-ftp-ftp] filename config.txt
```

Set the username to **admin** for the FTP server login.

```
[DeviceA-nqatplt-ftp-ftp] username admin
```

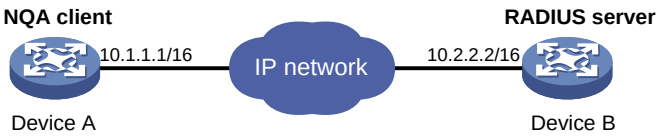
Set the password to **systemtest** for the FTP server login.

```
[DeviceA-nqatplt-ftp-ftp] password simple systemtest
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-ftp-ftp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.



```
[DeviceA-nqatplt-ftp-ftp] reaction trigger probe-fail 2
```

Example: Configuring the RADIUS template

Network configuration

As shown in Figure 25, configure a RADIUS template for a feature to test whether the RADIUS server (Device B) can provide authentication service for Device A. The username and password are **admin** and **systemtest**, respectively. The shared key is **123456** for secure RADIUS authentication.

Figure 25 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 25. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure the RADIUS server. (Details not shown.)

Create RADIUS template **radius**.

```
<DeviceA> system-view
[DeviceA] nqa template radius radius
```

Specify 10.2.2.2 as the destination IP address of the operation.

```
[DeviceA-nqatplt-radius-radius] destination ip 10.2.2.2
```

Set the username to **admin**.

```
[DeviceA-nqatplt-radius-radius] username admin
```

Set the password to **systemtest**.

```
[DeviceA-nqatplt-radius-radius] password simple systemtest
```

Set the shared key to **123456** in plain text for secure RADIUS authentication.

```
[DeviceA-nqatplt-radius-radius] key simple 123456
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-radius-radius] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-radius-radius] reaction trigger probe-fail 2
```

Example: Configuring the SSL template

Network configuration

As shown in Figure 26, configure an SSL template for a feature to test whether Device A can establish an SSL connection to the SSL server on Device B.

Figure 26 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 26. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure an SSL client policy named **abc** on Device A, and make sure Device A can use the policy to connect to the SSL server on Device B. (Details not shown.)

Create SSL template **ssl**.

```
<DeviceA> system-view
[DeviceA] nqa template ssl ssl
```

Set the destination IP address and port number to **10.2.2.2** and **9000**, respectively.

```
[DeviceA-nqatplt-ssl-ssl] destination ip 10.2.2.2
[DeviceA-nqatplt-ssl-ssl] destination port 9000
```

Specify SSL client policy **abc** for the SSL template.

```
[DeviceA-nqatplt-ssl-ssl] ssl-client-policy abc
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-ssl-ssl] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-ssl-ssl] reaction trigger probe-fail 2
```

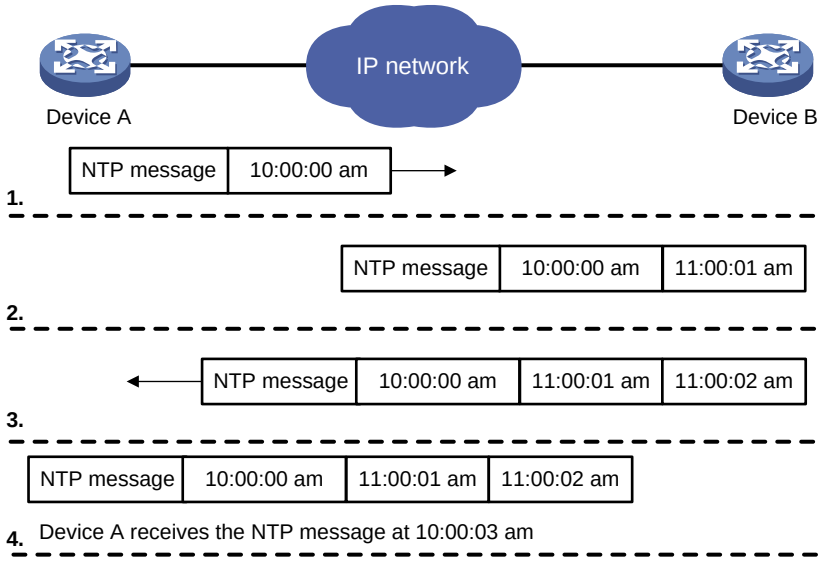
Configuring NTP

About NTP

NTP is used to synchronize system clocks among distributed time servers and clients on a network. NTP runs over UDP and uses UDP port 123.

NTP application scenarios

Various tasks, including network management, charging, auditing, and distributed computing depend on accurate and synchronized system time setting on the network devices. NTP is typically used in large networks to dynamically synchronize time among network devices.



NTP guarantees higher clock accuracy than manual system clock setting. In a small network that does not require high clock accuracy, you can keep time synchronized among devices by changing their system clocks one by one.

NTP working mechanism

Figure 1 shows how NTP synchronizes the system time between two devices (Device A and Device B, in this example). Assume that:

- Prior to the time synchronization, the time is set to 10:00:00 am for Device A and 11:00:00 am for Device B.
- Device B is used as the NTP server. Device A is to be synchronized to Device B.
- It takes 1 second for an NTP message to travel from Device A to Device B, and from Device B to Device A.
- It takes 1 second for Device B to process the NTP message.

Figure 1 Basic work flow

The synchronization process is as follows:

1. Device A sends Device B an NTP message, which is timestamped when it leaves Device A. The time stamp is 10:00:00 am (T1).

2. When this NTP message arrives at Device B, Device B adds a timestamp showing the time when the message arrived at Device B. The timestamp is 11:00:01 am (T2).
3. When the NTP message leaves Device B, Device B adds a timestamp showing the time when the message left Device B. The timestamp is 11:00:02 am (T3).
4. When Device A receives the NTP message, the local time of Device A is 10:00:03 am (T4).

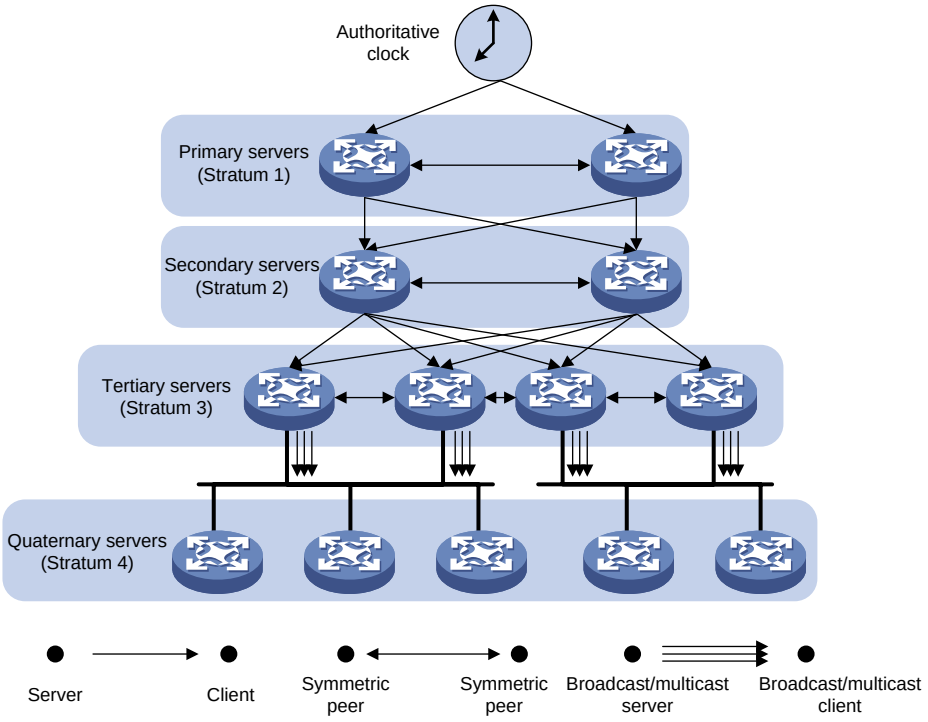
Up to now, Device A can calculate the following parameters based on the timestamps:

- The roundtrip delay of the NTP message: Delay = (T4 – T1) – (T3 – T2) = 2 seconds.
- Time difference between Device A and Device B: Offset = [(T2 – T1) + (T3 – T4)] /2 = 1 hour.

Based on these parameters, Device A can be synchronized to Device B.

This is only a rough description of the work mechanism of NTP. For more information, see the related protocols and standards.

NTP architecture



CAUTION:

When the device acts as an NTP client, the NTP server's clock stratum must be not smaller than 0 and not larger than 14. If the NTP server's clock stratum is larger than 14, the device will not synchronize with that server's clock. You can log in to the NTP server to change its clock stratum by executing the **`ntp-service refclock-master`** command.

- To check the stratum for an IPv4 NTP server, execute the **`display ntp-service sessions`** command on the device and check the **stra** field in the output.
- To check the stratum for an IPv6 NTP server, execute the **`display ntp-service ipv6 sessions`** command on the device and check the **Clock stratum** field in the output.

NTP uses stratums 0 to 16 to define clock accuracy, as shown in Figure 2. A lower stratum value represents higher accuracy.

Figure 2 NTP architecture

A stratum 1 NTP server gets its time from an authoritative time source, such as an atomic clock. It provides time for other devices as the primary NTP server. A stratum 2 time server receives its time from a stratum 1 time server, and so on.

To ensure time accuracy and availability, you can specify multiple NTP servers for a device. The device selects an optimal NTP server as the clock source based on parameters such as stratum. The clock that the device selects is called the reference source. For more information about clock selection, see the related protocols and standards.

If the devices in a network cannot synchronize to an authoritative time source, you can perform the following tasks:

- Select a device that has a relatively accurate clock from the network.
- Use the local clock of the device as the reference clock to synchronize other devices in the network.

NTP association modes

NTP supports the following association modes:

- Client/server mode
- Symmetric active/passive mode
- Broadcast mode
- Multicast mode

You can select one or more association modes for time synchronization. Table 1 provides detailed description for the four association modes.

In this document, an "NTP server" or a "server" refers to a device that operates as an NTP server in client/server mode. Time servers refer to all the devices that can provide time synchronization, including NTP servers, NTP symmetric peers, broadcast servers, and multicast servers.

Table 1 NTP association modes

Mode	Working process	Principle	Application scenario
Client/server	On the client, specify the IP address of the NTP server. A client sends a clock synchronization message to the NTP servers. Upon receiving the message, the servers automatically operate in server mode and send a reply. If the client can be synchronized to multiple time servers, it selects an optimal clock and synchronizes its local clock to the optimal reference source after receiving the replies from the servers.	A client can synchronize to a server, but a server cannot synchronize to a client.	As Figure 2 shows, this mode is intended for configurations where devices of a higher stratum synchronize to devices with a lower stratum.
Symmetric active/passive	On the symmetric active peer, specify the IP address of the symmetric passive peer. A symmetric active peer periodically sends clock synchronization messages to a symmetric passive peer. The symmetric passive peer automatically operates in symmetric passive mode and	A symmetric active peer and a symmetric passive peer can be synchronized to each other. If both of them are synchronized, the peer with a higher stratum is synchronized to the peer with a lower stratum.	As Figure 2 shows, this mode is most often used between servers with the same stratum to operate as a backup for one another. If a server fails to communicate with all the servers of a lower stratum, the server can still synchronize to the servers

Mode	Working process	Principle	Application scenario
	sends a reply. If the symmetric active peer can be synchronized to multiple time servers, it selects an optimal clock and synchronizes its local clock to the optimal reference source after receiving the replies from the servers.		of the same stratum.
Broadcast	A server periodically sends clock synchronization messages to the broadcast address 255.255.255.255. Clients listen to the broadcast messages from the servers to synchronize to the server according to the broadcast messages. When a client receives the first broadcast message, the client and the server start to exchange messages to calculate the network delay between them. Then, only the broadcast server sends clock synchronization messages.	A broadcast client can synchronize to a broadcast server, but a broadcast server cannot synchronize to a broadcast client.	A broadcast server sends clock synchronization messages to synchronize clients in the same subnet. As Figure 2 shows, broadcast mode is intended for configurations involving one or a few servers and a potentially large client population. The broadcast mode has lower time accuracy than the client/server and symmetric active/passive modes because only the broadcast servers send clock synchronization messages.
Multicast	A multicast server periodically sends clock synchronization messages to the user-configured multicast address. Clients listen to the multicast messages from servers and synchronize to the server according to the received messages.	A multicast client can synchronize to a multicast server, but a multicast server cannot synchronize to a multicast client.	A multicast server can provide time synchronization for clients in the same subnet or in different subnets. The multicast mode has lower time accuracy than the client/server and symmetric active/passive modes.

NTP security

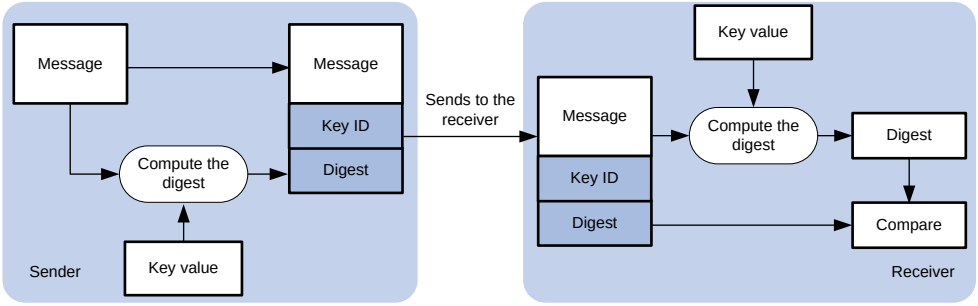
To improve time synchronization security, NTP provides the access control and authentication functions.

NTP access control

You can control NTP access by using an ACL. The access rights are in the following order, from the least restrictive to the most restrictive:

- **Peer**—Allows time requests and NTP control queries (such as alarms, authentication status, and time server information) and allows the local device to synchronize itself to a peer device.
- **Server**—Allows time requests and NTP control queries, but does not allow the local device to synchronize itself to a peer device.
- **Synchronization**—Allows only time requests from a system whose address passes the access list criteria.
- **Query**—Allows only NTP control queries from a peer device to the local device.

When the device receives an NTP request, it matches the request against the access rights in order from the least restrictive to the most restrictive: **peer**, **server**, **synchronization**, and **query**.



- If no NTP access control is configured, the **peer** access right applies.
- If the IP address of the peer device matches a **permit** statement in an ACL, the access right is granted to the peer device. If a **deny** statement or no ACL is matched, no access right is granted.
- If no ACL is specified for an access right or the ACL specified for the access right is not created, the access right is not granted.
- If none of the ACLs specified for the access rights is created, the **peer** access right applies.
- If none of the ACLs specified for the access rights contains rules, no access right is granted.

This feature provides minimal security for a system running NTP. A more secure method is NTP authentication.

NTP authentication

Use this feature to authenticate the NTP messages for security purposes. If an NTP message passes authentication, the device can receive it and get time synchronization information. If not, the device discards the message. This function makes sure the device does not synchronize to an unauthorized time server.

Figure 3 NTP authentication

As shown in Figure 3, NTP authentication is performed as follows:

1. The sender uses the key identified by the key ID to calculate a digest for the NTP message through the MD5/HMAC authentication algorithm. Then it sends the calculated digest together with the NTP message and key ID to the receiver.
2. Upon receiving the message, the receiver performs the following actions:
   a. Finds the key according to the key ID in the message.
   b. Uses the key and the MD5/HMAC authentication algorithm to calculate the digest for the message.
   c. Compares the digest with the digest contained in the NTP message.
      - If they are different, the receiver discards the message.
      - If they are the same and an NTP association is not required to be established, the receiver provides a response packet. For information about NTP associations, see "Configuring the maximum number of dynamic associations."
      - If they are the same and an NTP association is required to be established or has existed, the local device determines whether the sender is allowed to use the authentication ID. If the sender is allowed to use the authentication ID, the receiver accepts the message. If the sender is not allowed to use the authentication ID, the receiver discards the message.

Protocols and standards

- RFC 1305, *Network Time Protocol (Version 3) Specification, Implementation and Analysis*
- RFC 5905, *Network Time Protocol Version 4: Protocol and Algorithms Specification*

Restrictions and guidelines: NTP configuration

- You cannot configure both NTP and SNTP on the same device.
- NTP is supported only on Layer 3 VLAN interfaces.
- The NTP service and SNTP service are mutually exclusive. You can only enable either NTP service or SNTP service at a time.
- To avoid frequent time changes or even synchronization failures, do not specify more than one reference source on a network.
- For correct time synchronization, make sure the time difference between the system time and the NTP clock source is less than 68 years.

△ **CAUTION:**

When the device acts as an NTP client, the NTP server's clock stratum must be not smaller than 0 and not larger than 14. If the NTP server's clock stratum is larger than 14, the device will not synchronize with that server's clock. You can log in to the NTP server to change its clock stratum by executing the **`ntp-service refclock-master`** command.

- To check the stratum for an IPv4 NTP server, execute the **`display ntp-service sessions`** command on the device and check the **stra** field in the output.
- To check the stratum for an IPv6 NTP server, execute the **`display ntp-service ipv6 sessions`** command on the device and check the **Clock stratum** field in the output.

NTP tasks at a glance

To configure NTP, perform the following tasks:

1. Enabling the NTP service
2. Configuring NTP association mode
   - Configuring NTP in client/server mode
   - Configuring NTP in symmetric active/passive mode
   - Configuring NTP in broadcast mode
   - Configuring NTP in multicast mode
3. (Optional.) Configuring the local clock as the reference source
4. (Optional.) Configuring access control rights
5. (Optional.) Configuring NTP authentication
   - Configuring NTP authentication in client/server mode
   - Configuring NTP authentication in symmetric active/passive mode
   - Configuring NTP authentication in broadcast mode
   - Configuring NTP authentication in multicast mode
6. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets
7. (Optional.) Specifying the NTP time-offset thresholds for log and trap outputs

Enabling the NTP service

Restrictions and guidelines

NTP and SNTP are mutually exclusive. Before you enable NTP, make sure SNTP is disabled.

Procedure

1. Enter system view.

   system-view

2. Enable the NTP service.

   ntp-service enable

   By default, the NTP service is disabled.

Configuring NTP association mode

Configuring NTP in client/server mode

Restrictions and guidelines

To configure NTP in client/server mode, specify an NTP server for the client.

For a client to synchronize to an NTP server, make sure the server is synchronized by other devices or uses its local clock as the reference source.

If the stratum level of a server is higher than or equal to a client, the client will not synchronize to that server.

You can specify multiple servers for a client by executing the **ntp-service unicast-server** or **ntp-service ipv6 unicast-server** command multiple times.

Procedure

1. Enter system view.

   system-view

2. Specify an NTP server for the device.

   IPv4:

   ntp-service unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   ntp-service ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number*] *

   By default, no NTP server is specified.

Configuring NTP in symmetric active/passive mode

Restrictions and guidelines

To configure NTP in symmetric active/passive mode, specify a symmetric passive peer for the active peer.

For a symmetric passive peer to process NTP messages from a symmetric active peer, execute the **ntp-service enable** command on the symmetric passive peer to enable NTP.

For time synchronization between the symmetric active peer and the symmetric passive peer, make sure either or both of them are in synchronized state.

You can specify multiple symmetric passive peers by executing the **ntp-service unicast-peer** or **ntp-service ipv6 unicast-peer** command multiple times.

Procedure

1. Enter system view.

   system-view

2. Specify a symmetric passive peer for the device.

   IPv4:

   ntp-service unicast-peer { *peer-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   ntp-service ipv6 unicast-peer { *peer-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number*] *

   By default, no symmetric passive peer is specified.

Configuring NTP in broadcast mode

Restrictions and guidelines

To configure NTP in broadcast mode, you must configure an NTP broadcast client and an NTP broadcast server.

For a broadcast client to synchronize to a broadcast server, make sure the broadcast server is synchronized by other devices or uses its local clock as the reference source.

Configuring the broadcast client

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in broadcast client mode.

   ntp-service broadcast-client

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device receives NTP broadcast messages from the specified interface.

Configuring the broadcast server

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in NTP broadcast server mode.

ntp-service broadcast-server [**authentication-keyid** *keyid* | **version** *number*] *

By default, the device does not operate in any NTP association mode.

After you execute the command, the device sends NTP broadcast messages from the specified interface.

Configuring NTP in multicast mode

Restrictions and guidelines

To configure NTP in multicast mode, you must configure an NTP multicast client and an NTP multicast server.

For a multicast client to synchronize to a multicast server, make sure the multicast server is synchronized by other devices or uses its local clock as the reference source.

Configuring a multicast client

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in multicast client mode.

   IPv4:

   ntp-service multicast-client [*ip-address*]

   IPv6:

   ntp-service ipv6 multicast-client *ipv6-address*

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device receives NTP multicast messages from the specified interface.

Configuring the multicast server

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in multicast server mode.

   IPv4:

   ntp-service multicast-server [*ip-address*][**authentication-keyid** *keyid* | **ttl** *ttl-number* | **version** *number*]*

   IPv6:

   ntp-service ipv6 multicast-server *ipv6-address* [**authentication-keyid** *keyid* | **ttl** *ttl-number*] *

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device sends NTP multicast messages from the specified interface.

Configuring the local clock as the reference source

About this task

This task enables the device to use the local clock as the reference so that the device is synchronized.

Restrictions and guidelines

Make sure the local clock can provide the time accuracy required for the network. After you configure the local clock as the reference source, the local clock is synchronized, and can operate as a time server to synchronize other devices in the network. If the local clock is incorrect, timing errors occur.

The system time reverts to the initial BIOS default after a cold reboot. The system clock stops and does not record the passing of time during a warm reboot. As a best practice, do not configure the local clock as the reference source or configure the device as a time server.

Devices differ in clock precision. As a best practice to avoid network flapping and clock synchronization failure, configure only one reference clock on the same network segment and make sure the clock has high precision.

Prerequisites

Before you configure this feature, adjust the local system time to ensure that it is accurate.

Procedure

1. Enter system view.

   `system-view`

2. Configure the local clock as the reference source.

   `ntp-service refclock-master` [*`ip-address`*] [*`stratum`*]

   By default, the device does not use the local clock as the reference source.

Configuring access control rights

Prerequisites

Before you configure the right for peer devices to access the NTP services on the local device, create and configure ACLs associated with the access right. For information about configuring an ACL, see *ACL and QoS Configuration Guide*.

Restrictions and guidelines

Follow the restrictions and guidelines as described in Table 2 to configure the NTP access control rights.

Table 2 Restrictions and guidelines for configuring NTP access control rights

NTP access control right	Whether the time can be synchronized (whether configurable on a client)	Whether can synchronize the time of other devices (whether configurable on a time server)	Whether control queries are allowed
Peer	Yes	Yes	Yes
Server	No	Yes	Yes

Synchronization	No	Yes	No
Query	No	No	Yes

Procedure

1. Enter system view.

   system-view

2. Configure the right for peer devices to access the NTP services on the local device.

   IPv4:

   ntp-service access { **peer** | **query** | **server** | **synchronization** } **acl** *ipv4-acl-number*

   IPv6:

   ntp-service ipv6 { **peer** | **query** | **server** | **synchronization** } **acl** *ipv6-acl-number*

   By default, the right for peer devices to access the NTP services on the local device is **peer**.

Configuring NTP authentication

Configuring NTP authentication in client/server mode

Restrictions and guidelines

To ensure a successful NTP authentication in client/server mode, configure the same authentication key ID, algorithm, and key on the server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on client and server. For more information, see Table 3. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 3 NTP authentication results

Client			**Server**	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	N/A	N/A
Authentication not performed				
Yes	No	N/A	N/A	N/A
No	N/A	N/A	N/A	N/A

Configuring NTP authentication for a client

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Associate the specified key with an NTP server.

   IPv4:

   ntp-service unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

Configuring NTP authentication for a server

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication in symmetric active/passive mode

Restrictions and guidelines

To ensure a successful NTP authentication in symmetric active/passive mode, configure the same authentication key ID, algorithm, and key on the active peer and passive peer. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on active peer and passive peer. For more information, see Table 4. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 4 NTP authentication results

Active peer				Passive peer	
Enable NTP authentication	**Specify the peer and key**	**Trusted key**	**Stratum level**	**Enable NTP authentication**	**Trusted key**
Successful authentication					
Yes	Yes	Yes	N/A	Yes	Yes
Failed authentication					
Yes	Yes	Yes	N/A	Yes	No
Yes	Yes	Yes	N/A	No	N/A
Yes	No	N/A	N/A	Yes	N/A
No	N/A	N/A	N/A	Yes	N/A
Yes	Yes	No	Larger than the passive peer	N/A	N/A
Yes	Yes	No	Smaller than the passive peer	Yes	N/A
Authentication not performed					
Yes	No	N/A	N/A	No	N/A
No	N/A	N/A	N/A	No	N/A
Yes	Yes	No	Smaller than the passive peer	No	N/A

Configuring NTP authentication for an active peer

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Associate the specified key with a passive peer.

   IPv4:

   ntp-service unicast-peer { *ip-address* | *peer-name* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 unicast-peer { *ipv6-address* | *peer-name* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

Configuring NTP authentication for a passive peer

1. Enter system view.
   system-view
2. Enable NTP authentication.
   ntp-service authentication enable
   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.
   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *
   By default, no NTP authentication key exists.
4. Configure the key as a trusted key.
   ntp-service reliable authentication-keyid *keyid*
   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication in broadcast mode

Restrictions and guidelines

To ensure a successful NTP authentication in broadcast mode, configure the same authentication key ID, algorithm, and key on the broadcast server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on broadcast client and server. For more information, see Table 5. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 5 NTP authentication results

Broadcast server			Broadcast client	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	Yes	N/A
Yes	No	N/A	Yes	N/A
No	N/A	N/A	Yes	N/A
Authentication not performed				
Yes	Yes	No	No	N/A
Yes	No	N/A	No	N/A
No	N/A	N/A	No	N/A

Configuring NTP authentication for a broadcast client

1. Enter system view.
   system-view
2. Enable NTP authentication.
   ntp-service authentication enable
   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.
   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *
   By default, no NTP authentication key exists.
4. Configure the key as a trusted key.
   ntp-service reliable authentication-keyid *keyid*
   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication for a broadcast server

1. Enter system view.
   system-view
2. Enable NTP authentication.
   ntp-service authentication enable
   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.
   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *
   By default, no NTP authentication key exists.
4. Configure the key as a trusted key.
   ntp-service reliable authentication-keyid *keyid*
   By default, no authentication key is configured as a trusted key.
5. Enter interface view.
   interface *interface-type interface-number*
6. Associate the specified key with the broadcast server.
   ntp-service broadcast-server authentication-keyid *keyid*
   By default, the broadcast server is not associated with a key.

Configuring NTP authentication in multicast mode

Restrictions and guidelines

To ensure a successful NTP authentication in multicast mode, configure the same authentication key ID, algorithm, and key on the multicast server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on broadcast client and server. For more information, see Table 6. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 6 NTP authentication results

Multicast server			Multicast client	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	Yes	N/A
Yes	No	N/A	Yes	N/A
No	N/A	N/A	Yes	N/A
Authentication not performed				
Yes	Yes	No	No	N/A
Yes	No	N/A	No	N/A
No	N/A	N/A	No	N/A

Configuring NTP authentication for a multicast client

1. Enter system view.

   system-view
2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.
4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication for a multicast server

1. Enter system view.

   system-view
2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Enter interface view.

   interface *interface-type interface-number*

6. Associate the specified key with a multicast server.

   IPv4:

   ntp-service multicast-server [*ip-address*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 multicast-server *ipv6-multicast-address* **authentication-keyid** *keyid*

   By default, no multicast server is associated with the specified key.

Controlling NTP message sending and receiving

Specifying a source address for NTP messages

About this task

You can specify a source address for NTP messages directly or by specifying a source interface. If you specify a source interface for NTP messages, the device uses the IP address of the specified interface as the source address to send NTP messages.

Restrictions and guidelines

To prevent interface status changes from causing NTP communication failures, specify an interface that is always up as the source interface, a loopback interface for example.

When the device responds to an NTP request, the source IP address of the NTP response is always the IP address of the interface that has received the NTP request.

If you have specified the source interface for NTP messages in the **ntp-service unicast-server/ntp-service ipv6 unicast-server** or **ntp-service unicast-peer/ntp-service ipv6 unicast-peer** command, the IP address of the specified interface is used as the source IP address for NTP messages.

If you have configured the **ntp-service broadcast-server** or **ntp-service multicast-server/ntp-service ipv6 multicast-server** command in an interface view, the IP address of the interface is used as the source IP address for broadcast or multicast NTP messages.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for NTP messages.

   IPv4:

   ntp-service source { *interface-type interface-number* | *ipv4-address* }

   IPv6:

   ntp-service ipv6 source *interface-type interface-number*

   By default, no source address is specified for NTP messages.

Disabling an interface from receiving NTP messages

About this task

When NTP is enabled, all interfaces by default can receive NTP messages. For security purposes, you can disable some of the interfaces from receiving NTP messages.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Disable the interface from receiving NTP packets.

   IPv4:

   undo ntp-service inbound enable

   IPv6:

   undo ntp-service ipv6 inbound enable

   By default, an interface receives NTP messages.

Configuring the maximum number of dynamic associations

About this task

Perform this task to restrict the number of dynamic associations to prevent dynamic associations from occupying too many system resources.

NTP has the following types of associations:

- **Static association**—A manually created association.
- **Dynamic association**—Temporary association created by the system during NTP operation. A dynamic association is removed if no messages are exchanged within about 12 minutes.

The following describes how an association is established in different association modes:

- **Client/server mode**—After you specify an NTP server, the system creates a static association on the client. The server simply responds passively upon the receipt of a message, rather than creating an association (static or dynamic).
- **Symmetric active/passive mode**—After you specify a symmetric passive peer on a symmetric active peer, static associations are created on the symmetric active peer, and dynamic associations are created on the symmetric passive peer.
- **Broadcast or multicast mode**—Static associations are created on the server, and dynamic associations are created on the client.

Restrictions and guidelines

A single device can have a maximum of 128 concurrent associations, including static associations and dynamic associations.

The **ntp-service max-dynamic-sessions** command does not affect established NTP sessions. When the number of sessions reaches or exceeds the maximum allowed limit, no new sessions can be established.

Procedure

1. Enter system view.

   system-view
2. Configure the maximum number of dynamic sessions.

ntp-service max-dynamic-sessions *number*

By default, the maximum number of dynamic sessions is 100.

Setting a DSCP value for NTP packets

About this task

The DSCP value determines the sending precedence of an NTP packet. Through this configuration, you can specify the DSCP value of NTP packets sent by the device when it acts as an NTP/IPv6 NTP server or client.

Procedure

1. Enter system view.

   system-view

2. Set a DSCP value for NTP packets.

   IPv4:

   ntp-service dscp *dscp-value*

   IPv6:

   ntp-service ipv6 dscp *dscp-value*

   The default DSCP value is 48 for IPv4 packets and 56 for IPv6 packets.

Specifying the NTP time-offset thresholds for log and trap outputs

About this task

By default, the system synchronizes the NTP client's time to the server and outputs a log and a trap when the time offset exceeds 128 ms for multiple times.

After you set the NTP time-offset thresholds for log and trap outputs, the system synchronizes the client's time to the server when the time offset exceeds 128 ms for multiple times, but outputs logs and traps only when the time offset exceeds the specified thresholds, respectively.

Procedure

1. Enter system view.

   system-view

2. Specify the NTP time-offset thresholds for log and trap outputs.

   ntp-service time-offset-threshold { **log** *log-threshold* | **trap** *trap-threshold* } *

   By default, no NTP time-offset thresholds are set for log and trap outputs.

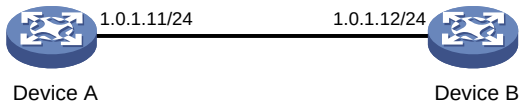
Display and maintenance commands for NTP

Execute **display** commands in any view.

Task	Command
Display information about IPv6 NTP associations.	**display ntp-service ipv6 sessions** [**verbose**]
Display information about IPv4 NTP associations.	**display ntp-service sessions**

Task	Command
	[**verbose**]
Display information about NTP service status.	**display ntp-service status**
Display brief information about the NTP servers from the local device back to the primary NTP server.	**display ntp-service trace** [**source** *interface-type interface-number*]

NTP configuration examples



Example: Configuring NTP client/server association mode

Network configuration

As shown in Figure 4, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the NTP server of Device B.

Figure 4 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 4. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```
3. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

   # Specify Device A as the NTP server of Device B.

   ```
   [DeviceB] ntp-service unicast-server 1.0.1.11
   ```

Verifying the configuration

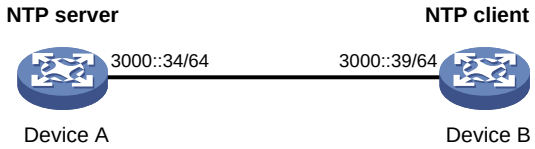
Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
```

```
System peer: 1.0.1.11
Local mode: client
Reference clock ID: 1.0.1.11
Leap indicator: 00
Clock jitter: 0.000977 s
Stability: 0.000 pps
Clock precision: 2^-10
Root delay: 0.00383 ms
Root dispersion: 16.26572 ms
Reference time: d0c6033f.b9923965  Wed, Dec 29 2019 18:58:07.724
System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Device B and Device A.

```
[DeviceB] display ntp-service sessions
      source          reference       stra reach poll  now offset  delay disper
**************************************************************************
[12345]1.0.1.11        127.127.1.0        2     1   64   15   -4.0 0.0038 16.262
Notes: 1 source(master), 2 source(peer), 3 selected, 4 candidate, 5 configured.
 Total sessions: 1
```



Example: Configuring IPv6 NTP client/server association mode

Network configuration

As shown in Figure 5, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the IPv6 NTP server of Device B.

Figure 5 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 5. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```

3. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   ```

```
[DeviceB] ntp-service enable
```

Specify NTP for obtaining the time.

```
[DeviceB] clock protocol ntp
```

Specify Device A as the IPv6 NTP server of Device B.

```
[DeviceB] ntp-service ipv6 unicast-server 3000::34
```

Verifying the configuration

Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3000::34
 Local mode: client

```

Example: Configuring NTP symmetric active/passive association mode

Network configuration

As shown in Figure 6, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device A to operate in symmetric active mode and specify Device B as the passive peer of Device A.

Figure 6 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 6. (Details not shown.)
2. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

3. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceA] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```

   # Configure Device B as its symmetric passive peer.

   ```
   [DeviceA] ntp-service unicast-peer 3.0.1.32
   ```

Verifying the configuration

Verify that Device B has synchronized its time with Device A.

```
[DeviceB] display ntp-service status
 Clock status: synchronized

Example: Configuring IPv6 NTP symmetric active/passive association mode

Network configuration

As shown in Figure 7, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device A to operate in symmetric active mode and specify Device B as the IPv6 passive peer of Device A.

Figure 7 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 7. (Details not shown.)
2. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```
3. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceA] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```

   # Configure Device B as the IPv6 symmetric passive peer.

   ```
   [DeviceA] ntp-service ipv6 unicast-peer 3000::36
   ```

Verifying the configuration

Verify that Device B has synchronized its time with Device A.

Example: Configuring NTP broadcast association mode

Network configuration

As shown in Figure 8, configure Switch C as the NTP server for multiple devices on the same network segment so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Switch A and Switch B to operate in broadcast client mode, and listen to broadcast messages on VLAN-interface 2.

Figure 8 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Switch A, Switch B, and Switch C can reach each other, as shown in Figure 8. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [SwitchC] ntp-service refclock-master 2
   ```

   # Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service broadcast-server
   ```

3. Configure Switch A:

   # Enable the NTP service.

   ```
   <SwitchA> system-view
   [SwitchA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchA] clock protocol ntp
   ```

   # Configure Switch A to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ntp-service broadcast-client
   ```

4. Configure Switch B:

   # Enable the NTP service.

   ```
   <SwitchB> system-view
   [SwitchB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchB] clock protocol ntp
   ```

   # Configure Switch B to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.

   ```
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ntp-service broadcast-client
   ```

Verifying the configuration

The following procedure uses Switch A as an example to verify the configuration.

Verify that Switch A has synchronized to Switch C, and the clock stratum level is 3 on Switch A and 2 on Switch C.

```
[SwitchA-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3.0.1.31
 Local mode: bclient
 Reference clock ID: 3.0.1.31
 Leap indicator: 00
 Clock jitter: 0.044281 s
 Stability: 0.000 pps
```

```
 Clock precision: 2^-10
 Root delay: 0.00229 ms
 Root dispersion: 4.12572 ms
 Reference time: d0d289fe.ec43c720  Sat, Jan  8 2019  7:00:14.922
 System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Switch A and Switch C.

```
[SwitchA-Vlan-interface2] display ntp-service sessions
       source          reference       stra reach poll  now offset  delay disper
**********************************************************************************

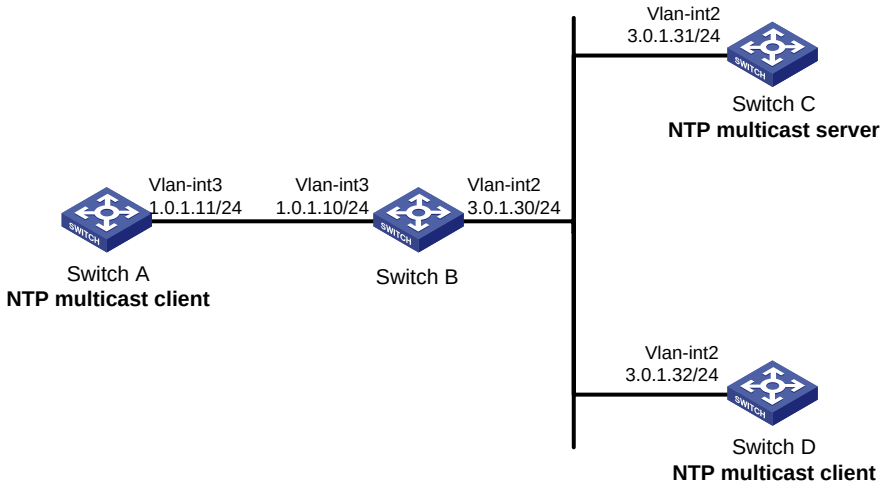
Notes: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured.
 Total sessions: 1
```



Example: Configuring NTP multicast association mode

Network configuration

As shown in Figure 9, configure Switch C as the NTP server for multiple devices on different network segments so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in multicast server mode and send multicast messages from VLAN-interface 2.
- Configure Switch A and Switch D to operate in multicast client mode and receive multicast messages on VLAN-interface 3 and VLAN-interface 2, respectively.

Figure 9 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure the switches can reach each other, as shown in Figure 9. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

```
[SwitchC] clock protocol ntp
```

Specify the local clock as the reference source, with stratum level 2.

```
[SwitchC] ntp-service refclock-master 2
```

Configure Switch C to operate in multicast server mode and send multicast messages from VLAN-interface 2.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ntp-service multicast-server
```

3. Configure Switch D:

Enable the NTP service.

```
<SwitchD> system-view
[SwitchD] ntp-service enable
```

Specify NTP for obtaining the time.

```
[SwitchD] clock protocol ntp
```

Configure Switch D to operate in multicast client mode and receive multicast messages on VLAN-interface 2.

```
[SwitchD] interface vlan-interface 2
[SwitchD-Vlan-interface2] ntp-service multicast-client
```

4. Verify the configuration:

Verify that Switch D has synchronized to Switch C, and the clock stratum level is 3 on Switch D and 2 on Switch C.

Switch D and Switch C are on the same subnet, so Switch D can receive the multicast messages from Switch C without being enabled with the multicast functions.

```
[SwitchD-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3.0.1.31
 Local mode: bclient
 Reference clock ID: 3.0.1.31
 Leap indicator: 00
 Clock jitter: 0.044281 s
 Stability: 0.000 pps
 Clock precision: 2^-10
 Root delay: 0.00229 ms
 Root dispersion: 4.12572 ms
 Reference time: d0d289fe.ec43c720  Sat, Jan  8 2019  7:00:14.922
 System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Switch D and Switch C.

```
[SwitchD-Vlan-interface2] display ntp-service sessions
      source          reference       stra reach poll  now offset  delay disper
**************************************************************************
 [1245]3.0.1.31        127.127.1.0        2     1   64  519   -0.0 0.0022 4.1257
Notes: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured.
 Total sessions: 1
```

5. Configure Switch B:

Because Switch A and Switch C are on different subnets, you must enable the multicast functions on Switch B before Switch A can receive multicast messages from Switch C.

Enable IP multicast functions.

```
<SwitchB> system-view
```

```
[SwitchB] multicast routing
[SwitchB-mrib] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] pim dm

Example: Configuring IPv6 NTP multicast association mode

Network configuration

As shown in Figure 10, configure Switch C as the NTP server for multiple devices on different network segments so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in IPv6 multicast server mode and send IPv6 multicast messages from VLAN-interface 2.
- Configure Switch A and Switch D to operate in IPv6 multicast client mode and receive IPv6 multicast messages on VLAN-interface 3 and VLAN-interface 2, respectively.

Figure 10 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure the switches can reach each other, as shown in Figure 10. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [SwitchC] ntp-service refclock-master 2
   ```

   # Configure Switch C to operate in IPv6 multicast server mode and send multicast messages from VLAN-interface 2.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service ipv6 multicast-server ff24::1
   ```

3. Configure Switch D:

   # Enable the NTP service.

   ```
   <SwitchD> system-view
   ```

```
[SwitchD] ntp-service enable
```

Specify NTP for obtaining the time.

```
[SwitchD] clock protocol ntp
```

Configure Switch D to operate in IPv6 multicast client mode and receive multicast messages on VLAN-interface 2.

```
[SwitchD] interface vlan-interface 2
[SwitchD-Vlan-interface2] ntp-service ipv6 multicast-client ff24::1
```

4. Verify the configuration:

Verify that Switch D has synchronized its time with Switch C, and the clock stratum level of Switch D is 3.

Switch D and Switch C are on the same subnet, so Switch D can Receive the IPv6 multicast messages from Switch C without being enabled with the IPv6 multicast functions.

```
[SwitchD-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3000::2
 Local mode: bclient
 Reference clock ID: 165.84.121.65
 Leap indicator: 00
 Clock jitter: 0.000977 s
 Stability: 0.000 pps
 Clock precision: 2^-10
 Root delay: 0.00000 ms
 Root dispersion: 8.00578 ms
 Reference time: d0c60680.9754fb17  Wed, Dec 29 2019 19:12:00.591
 System poll interval: 64 s
```

Verify that an IPv6 NTP association has been established between Switch D and Switch C.

```
[SwitchD-Vlan-interface2] display ntp-service ipv6 sessions

```

Example: Configuring NTP authentication in client/server association mode

Network configuration

As shown in Figure 11, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the NTP server of Device B.
- Configure NTP authentication on both Device A and Device B.

Figure 11 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 11. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```
3. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

   # Enable NTP authentication on Device B.

   ```
   [DeviceB] ntp-service authentication enable
   ```

   # Create a plaintext authentication key, with key ID **42** and key value **aNiceKey**.

   ```
   [DeviceB] ntp-service authentication-keyid 42 authentication-mode md5 simple
   aNiceKey
   ```

   # Specify the key as a trusted key.

   ```
   [DeviceB] ntp-service reliable authentication-keyid 42
   ```

   # Specify Device A as the NTP server of Device B, and associate the server with key 42.

   ```
   [DeviceB] ntp-service unicast-server 1.0.1.11 authentication-keyid 42
   ```

   To enable Device B to synchronize its clock with Device A, enable NTP authentication on Device A.
4. Configure NTP authentication on Device A:

   # Enable NTP authentication.

   ```
   [DeviceA] ntp-service authentication enable
   ```

   # Create a plaintext authentication key, with key ID **42** and key value **aNiceKey**.

```
[DeviceA] ntp-service authentication-keyid 42 authentication-mode md5 simple
aNiceKey
```

Specify the key as a trusted key.

```
[DeviceA] ntp-service reliable authentication-keyid 42
```

Verifying the configuration

Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 1.0.1.11
 Local mode: client
 Reference clock ID: 1.0.1.11

```

Example: Configuring NTP authentication in broadcast association mode

Network configuration

As shown in Figure 12, configure Switch C as the NTP server for multiple devices on the same network segment so that these devices synchronize the time with Switch C. Configure Switch A and Switch B to authenticate the NTP server.

- Configure Switch C's local clock as its reference source, with stratum level 3.
- Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Switch A and Switch B to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.
- Enable NTP authentication on Switch A, Switch B, and Switch C.

Figure 12 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Switch A, Switch B, and Switch C can reach each other, as shown in Figure 12. (Details not shown.)
2. Configure Switch A:

   # Enable the NTP service.

   ```
   <SwitchA> system-view
   [SwitchA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchA] clock protocol ntp
   ```

   # Enable NTP authentication on Switch A. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

   ```
   [SwitchA] ntp-service authentication enable
   [SwitchA] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
   [SwitchA] ntp-service reliable authentication-keyid 88
   ```

   # Configure Switch A to operate in NTP broadcast client mode and receive NTP broadcast messages on VLAN-interface 2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ntp-service broadcast-client
   ```

3. Configure Switch B:

   # Enable the NTP service.

   ```
   <SwitchB> system-view
   [SwitchB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchB] clock protocol ntp
   ```

   # Enable NTP authentication on Switch B. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

   ```
   [SwitchB] ntp-service authentication enable
   [SwitchB] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
   [SwitchB] ntp-service reliable authentication-keyid 88
   ```

   # Configure Switch B to operate in broadcast client mode and receive NTP broadcast messages on VLAN-interface 2.

   ```
   [SwitchB] interface vlan-interface 2
   ```

```
[SwitchB-Vlan-interface2] ntp-service broadcast-client
```

4. Configure Switch C:

Enable the NTP service.

```
<SwitchC> system-view
[SwitchC] ntp-service enable
```

Specify NTP for obtaining the time.

```
[SwitchC] clock protocol ntp
```

Specify the local clock as the reference source, with stratum level 3.

```
[SwitchC] ntp-service refclock-master 3
```

Configure Switch C to operate in NTP broadcast server mode and use VLAN-interface 2 to send NTP broadcast packets.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ntp-service broadcast-server
[SwitchC-Vlan-interface2] quit
```

5. Verify the configuration:

NTP authentication is enabled on Switch A and Switch B, but not on Switch C, so Switch A and Switch B cannot synchronize their local clocks to Switch C.

```
[SwitchB-Vlan-interface2] display ntp-service status
 Clock status: unsynchronized
 Clock stratum: 16
 Reference clock ID: none
```

6. Enable NTP authentication on Switch C:

Enable NTP authentication on Switch C. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

```
[SwitchC] ntp-service authentication enable
[SwitchC] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
[SwitchC] ntp-service reliable authentication-keyid 88
```

Specify Switch C as an NTP broadcast server, and associate key **88** with Switch C.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ntp-service broadcast-server authentication-keyid 88
```

Verifying the configuration

Verify that Switch B has synchronized its time with Switch C, and the clock stratum level of Switch B is 4.

```
[SwitchB-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 4
 System peer: 3.0.1.31
 Local mode: bclient
 Reference clock ID: 3.0.1.31
 Leap indicator: 00
 Clock jitter: 0.006683 s
 Stability: 0.000 pps

Configuring SNTP

About SNTP

SNTP is a simplified, client-only version of NTP specified in RFC 4330. It uses the same packet format and packet exchange procedure as NTP, but provides faster synchronization at the price of time accuracy.

SNTP working mode

SNTP supports only the client/server mode. An SNTP-enabled device can receive time from NTP servers, but cannot provide time services to other devices.

If you specify multiple NTP servers for an SNTP client, the server with the best stratum is selected. If multiple servers are at the same stratum, the NTP server whose time packet is first received is selected.

Protocols and standards

RFC 4330, *Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI*

Restrictions and guidelines: SNTP configuration

When you configure SNTP, follow these restrictions and guidelines:

- You cannot configure both NTP and SNTP on the same device.

SNTP tasks at a glance

To configure SNTP, perform the following tasks:

1. Enabling the SNTP service
2. Specifying an NTP server for the device
3. (Optional.) Configuring SNTP authentication
4. (Optional.) Specifying the SNTP time-offset thresholds for log and trap outputs

Enabling the SNTP service

Restrictions and guidelines

The NTP service and SNTP service are mutually exclusive. Before you enable SNTP, make sure NTP is disabled.

Procedure

1. Enter system view.

   `system-view`
2. Enable the SNTP service.

   `sntp enable`

   By default, the SNTP service is disabled.

Specifying an NTP server for the device

Restrictions and guidelines

To use an NTP server as the time source, make sure its clock has been synchronized. If the stratum level of the NTP server is greater than or equal to that of the client, the client does not synchronize with the NTP server.

Procedure

1. Enter system view.

   system-view

2. Specify an NTP server for the device.

   IPv4:

   sntp unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   sntp ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **source** *interface-type interface-number*] *

   By default, no NTP server is specified for the device.

   You can specify multiple NTP servers for the client by repeating this step.

   To perform authentication, you need to specify the **authentication-keyid** *keyid* option.

Configuring SNTP authentication

About this task

SNTP authentication ensures that an SNTP client is synchronized only to an authenticated trustworthy NTP server.

Restrictions and guidelines

Enable authentication on both the NTP server and the SNTP client.

Use the same authentication key ID, algorithm, and key on the NTP server and SNTP client. Specify the key as a trusted key on both the NTP server and the SNTP client. For information about configuring NTP authentication on an NTP server, see "Configuring NTP."

On the SNTP client, associate the specified key with the NTP server. Make sure the server is allowed to use the key ID for authentication on the client.

With authentication disabled, the SNTP client can synchronize with the NTP server regardless of whether the NTP server is enabled with authentication.

Procedure

1. Enter system view.

   system-view

2. Enable SNTP authentication.

   sntp authentication enable

   By default, SNTP authentication is disabled.

3. Configure an SNTP authentication key.

sntp authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*]*

By default, no SNTP authentication key exists.

4. Specify the key as a trusted key.

   sntp reliable authentication-keyid *keyid*

   By default, no trusted key is specified.

5. Associate the SNTP authentication key with an NTP server.

   IPv4:

   sntp unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   sntp ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   By default, no NTP server is specified.

Specifying the SNTP time-offset thresholds for log and trap outputs

About this task

By default, the system synchronizes the SNTP client's time to the server and outputs a log and a trap when the time offset exceeds 128 ms for multiple times.

After you set the SNTP time-offset thresholds for log and trap outputs, the system synchronizes the client's time to the server when the time offset exceeds 128 ms for multiple times, but outputs logs and traps only when the time offset exceeds the specified thresholds, respectively.

Procedure

1. Enter system view.

   system-view

2. Specify the SNTP time-offset thresholds for log and trap outputs.

   sntp time-offset-threshold { **log** *log-threshold* | **trap** *trap-threshold* } *

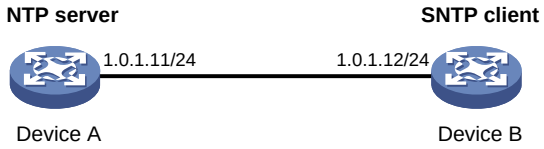
   By default, no SNTP time-offset thresholds are set for log and trap outputs.

Display and maintenance commands for SNTP

Execute **display** commands in any view.

Task	Command
Display information about all IPv6 SNTP associations.	**display sntp ipv6 sessions**
Display information about all IPv4 SNTP associations.	**display sntp sessions**

SNTP configuration examples



Example: Configuring SNTP

Network configuration

As shown in Figure 13, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in SNTP client mode, and specify Device A as the NTP server.
- Configure NTP authentication on Device A and SNTP authentication on Device B.

Figure 13 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 13. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceA] clock protocol ntp
   ```

   # Configure the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```

   # Enable NTP authentication on Device A.

   ```
   [DeviceA] ntp-service authentication enable
   ```

   # Configure a plaintext NTP authentication key, with key ID of **10** and key value of **aNiceKey**.

   ```
   [DeviceA] ntp-service authentication-keyid 10 authentication-mode md5 simple
   aNiceKey
   ```

   # Specify the key as a trusted key.

   ```
   [DeviceA] ntp-service reliable authentication-keyid 10
   ```

3. Configure Device B:

   # Enable the SNTP service.

   ```
   <DeviceB> system-view
   [DeviceB] sntp enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

   # Enable SNTP authentication on Device B.

   ```
   [DeviceB] sntp authentication enable
   ```

   # Configure a plaintext authentication key, with key ID of **10** and key value of **aNiceKey**.

   ```
   [DeviceB] sntp authentication-keyid 10 authentication-mode md5 simple aNiceKey
   ```

   # Specify the key as a trusted key.

```
[DeviceB] sntp reliable authentication-keyid 10
```

Specify Device A as the NTP server of Device B, and associate the server with key 10.

```
[DeviceB] sntp unicast-server 1.0.1.11 authentication-keyid 10
```

Verifying the configuration

Verify that an SNTP association has been established between Device B and Device A, and Device B has synchronized its time with Device A.

```
[DeviceB] display sntp sessions
NTP server     Stratum   Version    Last receive time
1.0.1.11        2         4          Tue, May 17 2019  9:11:20.833 (Synced)

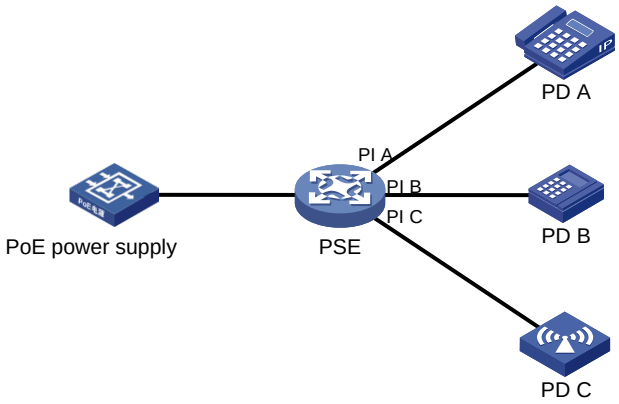
Configuring PoE

About PoE



Power over Ethernet (PoE) enables a network device to supply power to terminals over twisted pair cables.

PoE system

As shown in Figure 1, a PoE system includes the following elements:

- **PoE power supply**—A PoE power supply provides power for the entire PoE system.
- **PSE**—A power sourcing equipment (PSE) supplies power to PDs. PSE devices are classified into single-PSE devices and multiple-PSE devices.
  - A single-PSE device has only one piece of PSE firmware.
  - A multiple-PSE device has multiple PSEs. A multiple-PSE device uses PSE IDs to identify different PSEs. To view the mapping between the ID and slot number of a PSE, execute the **`display poe device`** command.
- **PI**—A power interface (PI) is a PoE-capable Ethernet interface on a PSE.
- **PD**—A powered device (PD) receives power from a PSE. PDs include IP telephones, APs, portable chargers, POS terminals, and Web cameras. You can also connect a PD to a redundant power source for reliability.

Figure 1 PoE system diagram

Protocols and standards

802.3af, 802.3at, and 802.3bt are the 3rd, 4th, and 5th editions of the PoE protocol established by the IEEE. The differences between the three PoE technologies lie in their power transmission capabilities and the number of wires used for power transmission.

- 802.3af, also known as the PoE standard, was released in 2003. It provides a maximum power output of 15.4 W and uses 2 pairs of wires for power transmission.

  The name of the 802.3af standard is *802.3af-2003, IEEE Standard for Information Technology - Telecommunications and Information Exchange Between Systems - Local and Metropolitan Area Networks - Specific Requirements - Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications - Data Terminal Equipment (DTE) Power Via Media Dependent Interface (MDI)*.

- 802.3at, also known as the PoE+ standard, was released in 2009. It provides a maximum power output of 30 W and uses 2 or 4 pairs of wires for power transmission. It is backward compatible with the 802.3af standard.

  The name of the *802.3at* standard is *802.3at-2009, IEEE Standard for Information technology-- Local and metropolitan area networks-- Specific requirements-- Part 3: CSMA/CD Access Method and Physical Layer Specifications Amendment 3: Data Terminal Equipment (DTE) Power via the Media Dependent Interface (MDI) Enhancements*.
- 802.3bt, also known as the PoE++ standard, was released in 2018. It provides a maximum power output of 90 W and is compatible with existing low-power PoE devices. This standard uses 4 pairs of wires for power transmission and supports PoE devices over long distances and with better performance. It is backward compatible with the 802.3af and 802.3at standards.
- The name of the 802.3bt standard is *802.3bt-2018 - IEEE Standard for Ethernet Amendment 2: Physical Layer and Management Parameters for Power over Ethernet over 4 pairs*.

Restrictions: Hardware compatibility with PoE

Only the PoE models support the PoE feature.

Restrictions and guidelines: PoE configuration

You can configure a PI through either of the following ways:

- Configure the settings directly on the PI.
- Configure a PoE profile and apply it to the PI. If you apply a PoE profile to multiple PIs, these PIs have the same PoE features. If you connect a PD to another PI, you can apply the PoE profile of the original PI to the new PI. This method relieves the task of configuring PoE on the new PI.

You can only use one way to configure a parameter for a PI. To use the other way to reconfigure a parameter, you must first remove the original configuration.

You must use the same configuration method for the **`poe max-power`** *`max-power`* and **`poe priority`** { **`critical`** | **`high`** | **`low`** } commands.

PoE configuration tasks at a glance

To configure PoE, perform the following tasks:

1. Enabling PoE
   a. Enabling PoE for a PI
2. (Optional.) Enabling fast PoE for a PSE
3. (Optional.) Allowing inrush currents drawn by PDs
4. (Optional.) Enabling PI power cycling upon a system warm reboot
5. (Optional.) Disabling PoE on shutdown interfaces
6. (Optional.) Configuring PD detection
   - Enabling nonstandard PD detection
7. (Optional.) Configuring the PoE power
   - Configuring the maximum PI power
8. (Optional.) Configuring the PoE priority policy
   - Configuring the PI priority policy

9. (Optional.) Configuring PoE monitoring
    - Monitoring PSE power
    - Monitoring PDs
10. (Optional.) Configuring a PI by using a PoE profile

    To use a PoE profile to enable PoE and configure the priority, power transmission mode, and maximum power for a PI, see "Configuring a PI by using a PoE profile."
11. (Optional.) Upgrading PSE firmware in service

Prerequisites for configuring PoE

Before you configure PoE, make sure the PoE power supply and PSEs are operating correctly.

Enabling PoE

Enabling PoE for a PI

About this task

After you enable PoE for a PI, the PI supplies power to the connected PD if the PI will not result in PSE power overload. PSE overload occurs when the sum of the power consumption of all PIs exceeds the maximum power of the PSE.

If the PI will result in PSE power overload, the following restrictions apply:

- If the PI priority policy is not enabled, the PI does not supply power to the connected PD.
- If the PI priority policy is enabled, whether the PDs can be powered depends on the priority of the PI.

For more information about the PI priority policy, see "Configuring the PI priority policy."

Power can be transmitted over a twisted pair cable in the following modes:

- **Signal pair mode**—Signal pairs (on pins 1, 2, 3, and 6) of the twisted pair cable are used for power transmission.
- **Spare pair mode**—Spare pairs (on pins 4, 5, 7, and 8) of the twisted pair cable are used for power transmission.

Restrictions and guidelines

A PI can supply power to a PD only when the PI and PD use the same power transmission mode.

When you specify a PoE standard for a PI, follow these restrictions and guidelines:

- For your configuration to take effect, restore the PI maximum power to the default before you configure this feature.
- IEEE PoE standards are not forward compatible. For a PI to supply power to PDs, make sure the PoE standard version of the PDs is the same as or earlier than the PoE standard version of the PI.
- If a PI operates in IEEE 802.3bt mode and supplies more than 30 W power, changing the PoE standard for the PI will cause the connected PDs to be power cycled. Be cautious when you modify the configuration of this feature.

Procedure

1. Enter system view.

   ```
   system-view
   ```
2. Enter PI view.

interface *interface-type interface-number*

3. (Optional.) Configure a description for the PD connected to the PI.

   poe pd-description *text*

   By default, no description is configured for the PD connected to the PI.

4. Enable PoE for the PI.

   poe enable

   By default, PoE is disabled on a PI.

Enabling AI-driven PoE

Restrictions and guidelines

AI-driven PoE takes effect only on PSEs that run firmware V147 or later.

- **PSEs with firmware earlier than V147**—You must use the **poe update** command to upgrade the PSE firmware and then enable AI-driven PoE on it.
- **PSEs with firmware V147 or later**—You do not need to re-enable AI-driven PoE after upgrading the firmware if you have enabled the feature before the upgrade.

Software version and feature compatibility

This feature is supported in R1122 and its later versions.

Procedure

1. Enter system view.

   system-view

2. Enable AI-driven PoE.

   poe ai enable

   By default, AI-driven PoE is disabled.

   AI-driven PoE automatically adjusts the power supply parameters to fit the power needs. If you disable AI-driven PoE, the system reverts the parameters to the settings before the adjustment.

Enabling fast PoE for a PSE

About this task

This feature enables a PI on a PSE to supply power to PDs immediately after the PSE is powered on.

Software version and feature compatibility

This feature is supported in R1122 and its later versions.

Procedure

1. Enter system view.

   system-view

2. Enable fast PoE for a PSE.

   poe fast-on enable pse *pse-id*

   By default, fast PoE is disabled on a PSE.

Allowing inrush currents drawn by PDs

About this task

Inrush current might occur at PD startup and trigger PSE self-protection, As a result, the PSE stops supplying power to the PDs. To continue power supply to the PDs, configure this feature to allow inrush current drawn by PDs.

IEEE 802.3af and IEEE 802.3at define specifications for inrush current. The device supports the specifications for inrush current defined by IEEE 802.3af and IEEE 802.3at.

Restrictions and guidelines

CAUTION:
Inrush current might damage device components. Use this feature with caution.

Procedure

1. Enter system view.
   `system-view`
2. Allow inrush current drawn by PDs.
   `poe high-inrush enable pse` *`pse-id`*
   By default, inrush current drawn by PDs is not allowed.

Enabling PI power cycling upon a system warm reboot

About this task

During the system warm reboot process (upon execution of the **`reboot`** command), the PIs continue supplying power to the PDs but data connections between the PDs and the device are interrupted. After the system reboots, PDs might not re-initiate data connections with the device. Power cycling PIs upon a system warm reboot allows the PDs to re-establish data connections with the device after a warm reboot.

Procedure

1. Enter system view.
   `system-view`
2. Enter PI power cycling upon a system warm reboot.
   `poe reset enable`
   By default, PI power cycling upon a system warm reboot is disabled.

Disabling PoE on shutdown interfaces

About this task

By default, the device continues supplying power to an interface after the interface is shut down by the **`shutdown`** command or by an upper layer module such as monitor link. As a result, the PD connected to the shutdown interface operates continuously but fails to access the network.

This task disables the PoE module from supplying power to an interface after the interface is shut down. After the interface comes up or you disable this task, the PoE module resumes power supply to the interface.

Software and feature compatibility

This feature is available only in R1132 and later versions.

Restrictions and guidelines

The task does not power off an interface that has been shut down but is supplying power to a PD.

Procedure

1. Enter system view.
   system-view
2. Disable PoE on shutdown interfaces.
   poe track-shutdown
   By default, PoE is not disabled on shutdown interfaces.

Configuring PD detection

Enabling nonstandard PD detection

About this task

PDs are classified into standard PDs and nonstandard PDs. Standard PDs are compliant with IEEE 802.3af and IEEE 802.3at. A PSE supplies power to a nonstandard PD only after nonstandard PD detection is enabled.

The device supports PSE-based and PI-based nonstandard PD detection. Enabling nonstandard PD detection for a PSE enables this feature for all PIs on the PSE. As a best practice for disabling nonstandard PD detection for all PIs successfully in one operation, disable this feature in both system view and interface view.

Procedure

1. Enter system view.
   system-view
2. Enable nonstandard PD detection. Choose one option as needed.
   - Enable nonstandard PD detection for the PSE.
     poe legacy enable pse *pse-id*
     By default, nonstandard PD detection is disabled for a PSE.
   - Execute the following commands in sequence to enable nonstandard PD detection for a PI:
     interface *interface-type interface-number*
     poe legacy enable
     By default, nonstandard PD detection is disabled for a PI.

Configuring a PD detection mode

About this task

The device detects PDs in one of the following modes:

- **None**—The device supplies power to PDs that are correctly connected to the device without causing short circuit.
- **Simple**—The device supplies power to PDs that comply with basic requirements of 802.3af or 802.3at.

- **Strict**—The device supplies power to PDs that comply with all requirements of 802.3af or 802.3at.

Restrictions and guidelines

CAUTION:

A non-PD device might be damaged when power is supplied to it. To avoid device damage, do not specify the **none** mode when the PI connects to a non-PD device.

For this feature to take effect on nonstandard PDs, you must enable detection for nonstandard PDs by using the **poe legacy enable** command.

Procedure

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Configure the PD detection mode.
   poe detection-mode { **none** | **simple** | **strict** }
   By default, the PD detection mode is strict.

Configuring the PoE power

Configuring the maximum PI power

About this task

The maximum PI power is the maximum power that a PI can provide to the connected PD. If the PD requires more power than the maximum PI power, the PI does not supply power to the PD.

Procedure

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Configure the maximum power for the PI.
   poe max-power *max-power*
   By default, In versions earlier than R1112, the maximum PI power is 30000 milliwatts. In R1112 and later, the maximum PI power is 35000 milliwatts..

Configuring the PoE priority policy

Configuring the PI priority policy

About this task

The PI priority policy enables the PSE to perform priority-based power allocation to PIs when PSE power overload occurs. The priority levels for PIs are critical, high, and low in descending order.

When PSE power overload occurs, the PSE supplies power to PDs as follows:

- If the PI priority policy is disabled, the PSE supplies power to PDs depending on whether you have configured the maximum PSE power.
  - If you have configured the maximum PSE power, the PSE does not supply power to the newly-added or existing PD that causes PSE power overload.
  - If you have not configured the maximum PSE power, the PoE self-protection mechanism is triggered. The PSE stops supplying power to all PDs.
- If the PI priority policy is enabled, the PSE supplies power to PDs as follows:
  - If a PD being powered causes PSE power overload, the PSE stops supplying power to the PD.
  - If a newly-added PD causes PSE power overload, the PSE supplies power to PDs in priority descending order of the PIs to which they are connected. If the newly-added PD and a PD being powered have the same priority, the PD being powered takes precedence. If multiple PIs being powered have the same priority, the PIs with smaller IDs takes precedence.

Restrictions and guidelines

Before you configure a PI with critical priority, make sure the remaining power from the maximum PSE power minus the maximum powers of the existing PIs with critical priority is greater than maximum power of the PI.

Configuration for a PI whose power is preempted remains unchanged.

Procedure

1. Enter system view.
   system-view
2. Enable the PI priority policy.
   poe pd-policy priority
   By default, the PI priority policy is disabled.
3. Enter PI view.
   interface *interface-type interface-number*
4. (Optional.) Configure a priority for the PI.
   poe priority { **critical** | **high** | **low** }
   By default, the priority for a PI is **low**.

Configuring PoE monitoring

Monitoring PSE power

About this task

The system monitors PSE power utilization and sends notification messages when PSE power utilization exceeds or drops below the threshold. If PSE power utilization crosses the threshold multiple times in succession, the system sends notification messages only for the first crossing. For more information about the notification message, see "Configuring SNMP."

Procedure

1. Enter system view.
   system-view
2. Configure a power alarm threshold for a PSE.
   poe utilization-threshold *value* **pse** *pse-id*
   By default, the power alarm threshold for a PSE is 80%.

Monitoring PDs

About this task

Application scenarios

Some PDs, for example, IP cameras, might become unresponsive or malfunction during operation. Due to the installation location of the cameras, restarting them might be inconvenient. With the PD monitoring feature (PoE watchdog), the device can automatically monitor the PDs around the clock to identify whether they become unresponsive or malfunction, and automatically restart them when necessary to ensure continuous operation and stability.

Operating mechanism

With PD monitoring enabled, the system automatically checks the traffic on a PI every 5 minutes. If no traffic change occurs in two consecutive checks, the system determines that one or more PDs connected to the PI are abnormal and generates a message for the administrator to check the PD status. If the traffic remains unchanged in the following 5 minutes, the system will disable and then re-enable PoE on that PI for the PDs to power cycle and recover.

Software and feature compatibility

This feature is available only in R1132 and later versions.

Procedure

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Enable PD monitoring.
   poe pd-monitor enable
   By default, PD monitoring is disabled.

Configuring a PI by using a PoE profile

Restrictions and guidelines

To modify a PoE profile applied on a PI, first remove the PoE profile from the PI.

You can configure a PI either on the PI or by using a PoE profile. The **poe max-power** *max-power* and **poe priority** { **critical** | **high** | **low** } commands must be configured using the same method.

Configuring a PoE profile

1. Enter system view.
   system-view
2. Create a PoE profile and enter its view.
   poe-profile *profile-name* [*index*]
   By default, no PoE profiles exist.
3. Enable PoE.
   poe enable
   By default, PoE is disabled.

4. (Optional.) Configure the maximum PI power.

   poe max-power *max-power*

   By default, In versions earlier than R1112, the maximum PI power is 30000 milliwatts. In R1112 and later, the maximum PI power is 35000 milliwatts.

5. (Optional.) Configure a PI priority.

   poe priority { **critical** | **high** | **low** }

   The default priority is **low**.

   This command takes effect only after the PI priority policy is enabled.

Applying a PoE profile

Restrictions and guidelines

You can apply a PoE profile to multiple PIs in system view or a single PI in PI view. If you perform the operation in both views for the same PI, the most recent operation takes effect.

You can apply only one PoE profile to a PI.

Applying a PoE profile in system view

1. Enter system view.

   system-view

2. Apply a PoE profile to PIs.

   apply poe-profile { **index** *index* | **name** *profile-name* } **interface** *interface-range*

   By default, a PoE profile is not applied to a PI.

Applying a PoE profile in PI view

1. Enter system view.

   system-view

2. Enter PI view.

   interface *interface-type interface-number*

3. Apply the PoE profile to the interface.

   apply poe-profile { **index** *index* | **name** *profile-name* }

   By default, a PoE profile is not applied to a PI.

Upgrading PSE firmware in service

About this task

You can upgrade the PSE firmware in service in the following modes:

- **Refresh mode**—Updates the PSE firmware without deleting it. You can use the refresh mode in most cases.
- **Full mode**—Deletes the current PSE firmware and reloads a new one. Use the full mode if the PSE firmware is damaged and you cannot execute any PoE commands.

Restrictions and guidelines

If the PSE firmware upgrade fails because of interruption such as a device reboot, you can restart the device and upgrade it in full mode again. After the upgrade, restart the device manually for the new PSE firmware to take effect.

Procedure

1. Enter system view.
   system-view
2. Upgrade the PSE firmware in service.
   poe update { **full** | **refresh** } *filename* [**pse** *pse-id*]

Enabling forced PoE power supply

About this task

Before supplying power to a PD, the device performs a detection of the PD. It supplies power to the PD only after the PD passes the detection. If the PD fails the detection but the power provided by the device meets the PD specifications, you can configure this task to enable forced power supply to the PD.

When a PI is supplying power to PDs, this command triggers the device to perform the following steps:

1. Immediately stop PoE power supply on the interface.
2. Wait for the interface to switch to forced power mode.
3. Automatically re-enable PoE power supply.

Software and feature compatibility

This feature is available only in R1132 and later versions.

Restrictions and guidelines

CAUTION:

- PSE in version 2018 does not support this feature. For PSE in version 1082 to support this feature, upgrade it to version 1089 or a later version.
- This task enables the device to supply power to a PD directly without performing a detection of the PD. To avoid damaging the PD, make sure the power provided by the device meets the PD specifications before configuring this task.
- If a PI is supplying PoE power, perform this task forcibly re-enables PoE on that PI.

Procedure

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Enable forced PoE power supply.
   poe force-power
   By default, forced PoE power supply is disabled.

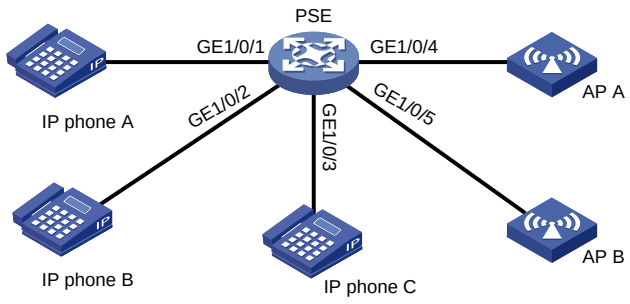
Display and maintenance commands for PoE

Execute **display** commands in any view.

Task	Command
Display general PSE information.	**display poe device** [**slot** *slot-number*]

Task	Command
Display the power supplying information for the specified PI.	**display poe interface** [*interface-type interface-number*]
Display power information for PIs.	**display poe interface power** [*interface-type interface-number*]
Display detailed PSE information.	**display poe pse** [*pse-id*]
Display the power supplying information for all PIs on a PSE.	**display poe pse** *pse-id* **interface**
Display power information for all PIs on a PSE.	**display poe pse** *pse-id* **interface power**
Display all information about the PoE profile.	**display poe-profile** [**index** *index* | **name** *profile-name*]
Display all information about the PoE profile applied to the specified PI.	**display poe-profile interface** *interface-type interface-number*

PoE configuration examples



Example: Configuring PoE

Network configuration

As shown in Figure 2, configure PoE to meet the following requirements:

- The device supplies power to IP phones and APs.
- IP phones take precedence to receive power when power overload occurs.
- Power supplied to AP B does not exceed 9000 milliwatts.

Figure 2 Network diagram

Procedure

Enable the PI priority policy.

```
<PSE> system-view
[PSE] poe pd-policy priority
```

Enable PoE on GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3, and configure their power supply priority as **critical**.

```
[PSE] interface gigabitethernet 1/0/1
[PSE-GigabitEthernet1/0/1] poe enable
[PSE-GigabitEthernet1/0/1] poe priority critical
```

```
[PSE-GigabitEthernet1/0/1] quit
[PSE] interface gigabitethernet 1/0/2
[PSE-GigabitEthernet1/0/2] poe enable
[PSE-GigabitEthernet1/0/2] poe priority critical
[PSE-GigabitEthernet1/0/2] quit
[PSE] interface gigabitethernet 1/0/3
[PSE-GigabitEthernet1/0/3] poe enable
[PSE-GigabitEthernet1/0/3] poe priority critical
[PSE-GigabitEthernet1/0/3] quit
```

Enable PoE on GigabitEthernet 1/0/4 and GigabitEthernet 1/0/5, and set the maximum power of GigabitEthernet 1/0/5 to 9000 milliwatts.

```
[PSE] interface gigabitethernet 1/0/4
[PSE-GigabitEthernet1/0/4] poe enable
[PSE-GigabitEthernet1/0/4] quit
[PSE] interface gigabitethernet 1/0/5
[PSE-GigabitEthernet1/0/5] poe enable
[PSE-GigabitEthernet1/0/5] poe max-power 9000
```

Verifying the configuration

Verify that the device is supplying power correctly to the IP phones and APs, and the IP phones and APs are operating correctly.

Troubleshooting PoE

Failure to set the priority of a PI to critical

Symptom

Power supply priority configuration for a PI failed.

Solution

To resolve the issue:

1. Identify whether the remaining guaranteed power of the PSE is lower than the maximum power of the PI. If it is, increase the maximum PSE power or reduce the maximum power of the PI.
2. Identify whether the priority has been configured through other methods. If the priority has been configured, remove the configuration.
3. If the issue persists, contact Technical Support.

Failure to apply a PoE profile to a PI

Symptom

PoE profile application for a PI failed.

Solution

To resolve the issue:

1. Identify whether some settings in the PoE profile have been configured. If they have been configured, remove the configuration.
2. Identify whether the settings in the PoE profile meet the requirements of the PI. If they do not, modify the settings in the PoE profile.

3. Identify whether another PoE profile is already applied to the PI. If it is, remove the application.
4. If the issue persists, contact Technical Support.

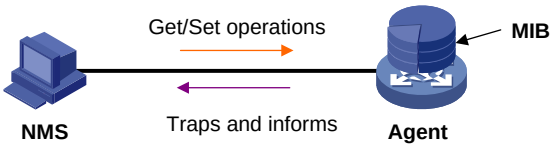
Configuring SNMP

About SNMP

Simple Network Management Protocol (SNMP) is used for a management station to access and operate the devices on a network, regardless of their vendors, physical characteristics, and interconnect technologies.



SNMP enables network administrators to read and set the variables on managed devices for state monitoring, troubleshooting, statistics collection, and other management purposes.

SNMP framework

The SNMP framework contains the following elements:

- **SNMP manager**—Works on an NMS to monitor and manage the SNMP-capable devices in the network. It can get and set values of MIB objects on an agent.
- **SNMP agent**—Works on a managed device to receive and handle requests from the NMS, and sends notifications to the NMS when events, such as an interface state change, occur.
- **Management Information Base (MIB)**—Specifies the variables (for example, interface status and CPU usage) maintained by the SNMP agent for the SNMP manager to read and set.

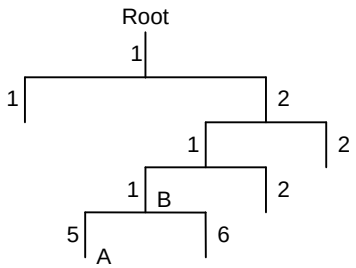


Figure 1 Relationship between NMS, agent, and MIB

MIB and view-based MIB access control

A MIB stores variables called "nodes" or "objects" in a tree hierarchy and identifies each node with a unique OID. An OID is a dotted numeric string that uniquely identifies the path from the root node to a leaf node. For example, object B in Figure 2 is uniquely identified by the OID {1.2.1.1}.

Figure 2 MIB tree

A MIB view represents a set of MIB objects (or MIB object hierarchies) with certain access privileges and is identified by a view name. The MIB objects included in the MIB view are accessible while those excluded from the MIB view are inaccessible.

A MIB view can have multiple view records each identified by a *view-name oid-tree* pair.

You control access to the MIB by assigning MIB views to SNMP groups or communities.

SNMP operations

SNMP provides the following basic operations:

- **Get**—NMS retrieves the value of an object node in an agent MIB.
- **Set**—NMS modifies the value of an object node in an agent MIB.
- **Notification**—SNMP notifications include traps and informs. The SNMP agent sends traps or informs to report events to the NMS. The difference between these two types of notification is that informs require acknowledgment but traps do not. Informs are more reliable but are also resource-consuming. Traps are available in SNMPv1, SNMPv2c, and SNMPv3. Informs are available only in SNMPv2c and SNMPv3.

Protocol versions

The device supports SNMPv1, SNMPv2c, and SNMPv3 in non-FIPS mode and supports only SNMPv3 in FIPS mode. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

- **SNMPv1**—Uses community names for authentication. To access an SNMP agent, an NMS must use the same community name as set on the SNMP agent. If the community name used by the NMS differs from the community name set on the agent, the NMS cannot establish an SNMP session to access the agent or receive traps from the agent.
- **SNMPv2c**—Uses community names for authentication. SNMPv2c is compatible with SNMPv1, but supports more operation types, data types, and error codes.
- **SNMPv3**—Uses a user-based security model (USM) to secure SNMP communication. You can configure authentication and privacy mechanisms to authenticate and encrypt SNMP packets for integrity, authenticity, and confidentiality.

Access control modes

SNMP uses the following modes to control access to MIB objects:

- **View-based Access Control Model**—VACM mode controls access to MIB objects by assigning MIB views to SNMP communities or users.
- **Role based access control**—RBAC mode controls access to MIB objects by assigning user roles to SNMP communities or users.
    - SNMP communities or users with predefined user role network-admin or level-15 have read and write access to all MIB objects.
    - SNMP communities or users with predefined user role network-operator have read-only access to all MIB objects.
    - SNMP communities or users with a user-defined user role have access rights to MIB objects as specified by the **`rule`** command.

RBAC mode controls access on a per MIB object basis, and VACM mode controls access on a MIB view basis. As a best practice to enhance MIB security, use the RBAC mode.

If you create the same SNMP community or user with both modes multiple times, the most recent configuration takes effect. For more information about RBAC, see *Fundamentals Command Reference*.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

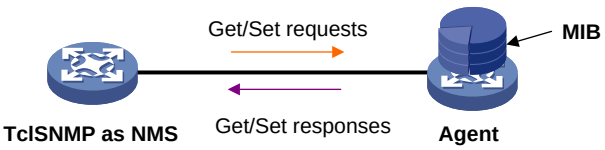
SNMP tasks at a glance

The device can act as an SNMP NMS and SNMP agent at the same time.

When the device acts as an SNMP NMS, perform the following tasks:

Configuring the device as an NMS

When the device acts as an SNMP agent, perform the following tasks:



1. Enabling the SNMP agent
2. Enabling SNMP versions
3. Configuring SNMP basic parameters
   - (Optional.) Configuring SNMP common parameters
   - Configuring an SNMPv1 or SNMPv2c community
   - Configuring an SNMPv3 group and user
4. (Optional.) Configuring SNMP notifications
5. (Optional.) Examining the system configuration for changes
6. (Optional.) Configuring SNMP logging

Configuring the device as an NMS

About this task

The device supports TclSNMP functionality based on Tcl version 8.5. Once the corresponding Lib file for TclSNMP is loaded, the device can function as an NMS. Network administrators can use standard Tcl scripts on this device to perform SNMP operations, such as get and set, on other network devices, thus checking the SNMP agent functionality on the target device or performing simple SNMP management tasks.

Figure 3 TclSNMP networking

Restrictions and guidelines

TclSNMP supports SNMP v1 and v2c.

TclSNMP does not support sending SNMP notifications.

Procedure

1. Enter Tcl configuration view from user view.

   `tclsh`

   For more information about this command, see *Fundamentals Command Reference*.
2. Load Lib file libtclsnmptools.so for the TclSNMP functionality.

   `load libtclsnmptools.so`

   The libtclsnmptools.so file is integrated in the System software package and does not require downloading.

   The `load` command is a standard Tcl command. For more information about the usage of this command, see the Tcl official documents.
3. Execute the corresponding SNMP Tcl script.

tclsnmp-command

Configuration examples

Use TclSNMP to retrieve the uptime of the target device (IP address 192.168.1.1) to verify if SNMP agent is functioning properly on the target device. The **load**, **snmpagent session**, and *xxx* **get** are standard Tcl commands, where *xxx* represents the SNMP session name.

```
<Sysname-tcl> tclsh
<Sysname-tcl> load libtclsnmptools.so
<Sysname-tcl> snmpagent session xxx -v2c -c public 192.168.1.1
<Sysname-tcl> xxx get 1.3.6.1.2.1.1.3.0
```

If information of the following format is displayed after you execute the above commands, it indicates that SNMP agent is functioning normally on the target device.

```
{.1.3.6.1.2.1.1.3.0 = Timeticks: (273076) 0:45:30.76}
```

Enabling the SNMP agent

Restrictions and guidelines

The SNMP agent is enabled when you use any command that begins with **snmp-agent** except for the **snmp-agent calculate-password** command.

The SNMP agent will fail to be enabled when the port that the agent will listen on is used by another service. You can use the **snmp-agent port** command to specify a listening port. To view the UDP port use information, execute the **display udp verbose** command. For more information about the **display udp verbose** command, see IP performance optimization commands in *Layer 3—IP Services Configuration Guide*.

If you disable the SNMP agent, the SNMP settings do not take effect. The **display current-configuration** command does not display the SNMP settings and the SNMP settings will not be saved in the configuration file. For the SNMP settings to take effect, enable the SNMP agent.

Procedure

1. Enter system view.

   system-view
2. Enable the SNMP agent.

   snmp-agent

   By default, the SNMP agent is disabled.

Enabling SNMP versions

Restrictions and guidelines

The device supports SNMPv1, SNMPv2c, and SNMPv3 in non-FIPS mode and supports only SNMPv3 in FIPS mode. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

The community name and data carried in SNMPv1 and SNMPv2c messages are in plaintext form, putting the SNMP communication at risks. As a best practice, use SNMPv3.

To use SNMP notifications in IPv6, enable SNMPv2c or SNMPv3.

Procedure

1. Enter system view.

system-view

2. Enable SNMP versions.

   In non-FIPS mode:

   snmp-agent sys-info version { **all** | { **v1** | **v2c** | **v3** } * }

   In FIPS mode:

   snmp-agent sys-info version v3

   By default, SNMPv3 is enabled.

   If you execute the command multiple times with different options, all the configurations take effect, but only one SNMP version is used by the agent and NMS for communication.

Configuring SNMP common parameters

Restrictions and guidelines

- SNMP engine ID

  An SNMP engine ID uniquely identifies a device in an SNMP managed network. Make sure the local SNMP engine ID is unique within your SNMP managed network to avoid communication problems. By default, the device is assigned a unique SNMP engine ID.

  If you have configured SNMPv3 users, change the local SNMP engine ID only when necessary. The change can void the SNMPv3 usernames and encrypted keys you have configured.

- SNMP listening port

  The SNMP agent will fail to be enabled when the port that the agent will listen on is used by another service. You can use the **snmp-agent port** command to change the SNMP listening port. As a best practice, execute the **display udp verbose** command to view the UDP port use information before specifying a new SNMP listening port. For more information about the **display udp verbose** command, see IP performance optimization commands in *Layer 3—IP Services Configuration Guide*.

- MIB view

  You can delete the default view by using the **undo snmp-agent mib-view** command. Be cautious with deleting the default MIB view. The operation blocks the access to any MIB object on the device from NMSs that use the default view. To restore the default view, restart the device.

  If you create a new MIB view, specify both permitted and excluded nodes by using the **snmp-agent mib-view** command. If the MIB view defines only excluded nodes, users bound to this view cannot access any device nodes.

  To bind MIB views, execute the **snmp-agent community** or **snmp-agent group** command.

Procedure

1. Enter system view.

   system-view

2. Specify an SNMP listening port.

   snmp-agent port *port-number*

   By default, the SNMP listening port is UDP port 161.

3. Set a local SNMP engine ID.

   snmp-agent local-engineid *engineid*

   By default, the local SNMP engine ID is the company ID plus the device ID.

4. Set an engine ID for a remote SNMP entity.

snmp-agent remote { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **engineid** *engineid*

By default, no remote entity engine IDs exist.

This step is required for the device to send SNMPv3 notifications to a host, typically NMS.

5. Create or update a MIB view.

   snmp-agent mib-view { **excluded** | **included** } *view-name oid-tree* [**mask** *mask-value*]

   By default, the MIB view **ViewDefault** is predefined. In this view, all the MIB objects in the **iso** subtree but the **snmpUsmMIB**, **snmpVacmMIB**, and **snmpModules.18** subtrees are accessible.

   Each *view-name oid-tree* pair represents a view record. If you specify the same record with different MIB sub-tree masks multiple times, the most recent configuration takes effect.

6. Configure the system management information.
   - Configure the system contact.

     snmp-agent sys-info contact *sys-contact*

     By default, the system contact is **New H3C Technologies Co., Ltd.**.
   - Configure the system location.

     snmp-agent sys-info location *sys-location*

     By default, the system location is **Hangzhou, China**.

7. Create an SNMP context.

   snmp-agent context *context-name*

   By default, no SNMP contexts exist.

8. Configure the maximum SNMP packet size (in bytes) that the SNMP agent can handle.

   snmp-agent packet max-size *byte-count*

   By default, an SNMP agent can process SNMP packets with a maximum size of 1500 bytes.

9. Set the DSCP value for SNMP responses.

   snmp-agent packet response dscp *dscp-value*

   By default, the DSCP value for SNMP responses is 0.

Configuring an SNMPv1 or SNMPv2c community

About configuring an SNMPv1 or SNMPv2c community

You can create an SNMPv1 or SNMPv2c community by using a community name or by creating an SNMPv1 or SNMPv2c user. After you create an SNMPv1 or SNMPv2c user, the system automatically creates a community by using the username as the community name.

Restrictions and guidelines for configuring an SNMPv1 or SNMPv2c community

SNMPv1 and SNMPv2c settings are not supported in FIPS mode.

Make sure the NMS and agent use the same SNMP community name.

Only users with the network-admin or level-15 user role can create SNMPv1 or SNMPv2c communities, users, or groups. Users with other user roles cannot create SNMPv1 or SNMPv2c communities, users, or groups even if these roles are granted access to related commands or commands of the SNMPv1 or SNMPv2c feature.

Configuring an SNMPv1/v2c community by a community name

1. Enter system view.

   system-view

2. Create an SNMPv1/v2c community. Choose one option as needed.

   - In VACM mode:

     snmp-agent community { **read** | **write** } [**simple** | **cipher**] *community-name* [**mib-view** *view-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent community [**simple** | **cipher**] *community-name* **user-role** *role-name* [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Map the SNMP community name to an SNMP context.

   snmp-agent community-map *community-name* **context** *context-name*

Configuring an SNMPv1/v2c community by creating an SNMPv1/v2c user

1. Enter system view.

   system-view

2. Create an SNMPv1/v2c group.

   snmp-agent group { **v1** | **v2c** } *group-name* [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. Add an SNMPv1/v2c user to the group.

   snmp-agent usm-user { **v1** | **v2c** } *user-name group-name* [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   The system automatically creates an SNMP community by using the username as the community name.

4. (Optional.) Map the SNMP community name to an SNMP context.

   snmp-agent community-map *community-name* **context** *context-name*

Configuring an SNMPv3 group and user

Restrictions and guidelines for configuring an SNMPv3 group and user

Restrictions and guidelines for privilege configuration

Only users with the network-admin or level-15 user role can create SNMPv3 users or groups.Users with other user roles cannot create SNMPv3 users or groups even if these roles are granted access to related commands or commands of the SNMPv3 feature.

Restrictions and guidelines for security level configuration

All users in an SNMP group share the security level and access rights of the group.

SNMPv3 supports the following security levels, from highest to lowest:

- **Privacy**—Authentication and encryption.
- **Authentication**—Authentication but no encryption.
- **None**—No authentication or encryption.

When you create an SNMP user group or SNMPv3 user on the device, you can specify a security level. You can also specify a security level on the NMS. The following requirements must be met when you specify a security level:

- For an SNMP connection to be established successfully, make sure the security level you specify is the same or in descending order of security for the SNMP user, on the NMS, and for the SNMP user group. If the security level is different, the security level specified on the NMS applies.
- If the security level specified on the NMS requires authentication, the security level of the SNMPv3 user must also require authentication, and the authentication password and algorithm configured on the device must match those specified on the NMS.
- If the security level specified on the NMS requires encryption, the security level of the SNMPv3 user must also require encryption, and the encryption password and algorithm configured on the device must match those specified on the NMS.

Configuring an SNMPv3 group and user in non-FIPS mode

1. Enter system view.

   system-view

2. Create an SNMPv3 group.

   snmp-agent group v3 *group-name* [**authentication** | **privacy**] [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Calculate the encrypted form for the key in plaintext form.

   snmp-agent calculate-password *plain-password* **mode** { **3desmd5** | **3dessha** | **aes192md5** | **aes192sha** | **aes256md5** | **aes256sha** | **md5** | **sha** } { **local-engineid** | **specified-engineid** *engineid* }

4. Create an SNMPv3 user. Choose one option as needed.
   - In VACM mode:

     snmp-agent usm-user v3 *user-name group-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [{ **cipher** | **simple** } **authentication-mode** { **md5** | **sha** } *auth-password* [**privacy-mode** { **3des** | **aes128** | **aes192** | **aes256** | **des56** } *priv-password*]] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent usm-user v3 *user-name* **user-role** *role-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [{ **cipher** | **simple** } **authentication-mode** { **md5** | **sha** } *auth-password* [**privacy-mode** { **3des** | **aes128** | **aes192** | **aes256** | **des56** } *priv-password*]] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

To send notifications to an SNMPv3 NMS, you must specify the **remote** keyword.

5. (Optional.) Assign a user role to the SNMPv3 user created in RBAC mode.

   snmp-agent usm-user v3 *user-name* **user-role** *role-name*

   By default, an SNMPv3 user has the user role assigned to it at its creation.

Configuring an SNMPv3 group and user in FIPS mode

1. Enter system view.

   system-view

2. Create an SNMPv3 group.

   snmp-agent group v3 *group-name* { **authentication** | **privacy** } [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Calculate the encrypted form for the key in plaintext form.

   snmp-agent calculate-password *plain-password* **mode** { **aes192sha** | **aes256sha** | **sha** } { **local-engineid** | **specified-engineid** *engineid* }

4. Create an SNMPv3 user. Choose one option as needed.

   - In VACM mode:

     snmp-agent usm-user v3 *user-name group-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] { **cipher** | **simple** } **authentication-mode sha** *auth-password* [**privacy-mode** { **aes128** | **aes192** | **aes256** } *priv-password*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent usm-user v3 *user-name* **user-role** *role-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] { **cipher** | **simple** } **authentication-mode sha** *auth-password* [**privacy-mode** { **aes128** | **aes192** | **aes256** } *priv-password*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   To send notifications to an SNMPv3 NMS, you must specify the **remote** keyword.

5. (Optional.) Assign a user role to the SNMPv3 user created in RBAC mode.

   snmp-agent usm-user v3 *user-name* **user-role** *role-name*

   By default, an SNMPv3 user has the user role assigned to it at its creation.

Configuring SNMP notifications

About SNMP notifications

The SNMP agent sends notifications (traps and informs) to inform the NMS of significant events, such as link state changes and user logins or logouts. After you enable notifications for a module, the module sends the generated notifications to the SNMP agent. The SNMP agent sends the received notifications as traps or informs based on the current configuration. Unless otherwise stated, the **trap** keyword in the command line includes both traps and informs.

Enabling SNMP notifications

Restrictions and guidelines

Enable an SNMP notification only if necessary. SNMP notifications are memory-intensive and might affect device performance.

To generate linkUp or linkDown notifications when the link state of an interface changes, you must perform the following tasks:

- Enable linkUp or linkDown notification globally by using the **snmp-agent trap enable standard** [**linkdown** | **linkup**] * command.
- Enable linkUp or linkDown notification on the interface by using the **enable snmp trap updown** command.

After you enable notifications for a module, whether the module generates notifications also depends on the configuration of the module. For more information, see the configuration guide for each module.

To use SNMP notifications in IPv6, enable SNMPv2c or SNMPv3.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications.

   snmp-agent trap enable [**configuration** | *protocol* | **standard** [**authentication** | **coldstart** | **linkdown** | **linkup** | **warmstart**] * | **system**]

   By default, configuration change notifications, SNMP standard notifications, and system notifications are enabled. For the SNMP notifications enabling status for other modules, see the module guide.

   For the device to send SNMP notifications for a protocol, first enable the protocol.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable link state notifications.

   enable snmp trap updown

   By default, link state notifications are enabled.

Configuring parameters for sending SNMP notifications

About this task

You can configure the SNMP agent to send notifications as traps or informs to a host, typically an NMS, for analysis and management. Traps are less reliable and use fewer resources than informs, because an NMS does not send an acknowledgment when it receives a trap.

When network congestion occurs or the destination is not reachable, the SNMP agent buffers notifications in a queue. You can set the queue size and the notification lifetime (the maximum time that a notification can stay in the queue). When the queue size is reached, the system discards the new notification it receives. If modification of the queue size causes the number of notifications in the queue to exceed the queue size, the oldest notifications are dropped for new notifications. A notification is deleted when its lifetime expires.

You can extend standard linkUp/linkDown notifications to include interface description and interface type, but must make sure the NMS supports the extended SNMP messages.

Configuring the parameters for sending SNMP traps

1. Enter system view.

   system-view

2. Configure a target host.

   In non-FIPS mode:

   snmp-agent target-host trap address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**dscp** *dscp-value*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* [**v1** | **v2c** | **v3** [**authentication** | **privacy**]]

   In FIPS mode:

   snmp-agent target-host trap address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**dscp** *dscp-value*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* **v3** { **authentication** | **privacy** }

   By default, no target host is configured.

   SNMPv1 does not support IPv6 networks. For the configuration to take effect, avoid specifying both the **ipv6** and **v1** keywords in the same command.

3. (Optional.) Configure a source address for sending traps.

   snmp-agent trap source *interface-type interface-number*

   By default, SNMP uses the IP address of the outgoing routed interface as the source IP address.

Configuring the parameters for sending SNMP informs

1. Enter system view.

   system-view

2. Configure a target host.

   In non-FIPS mode:

   snmp-agent target-host inform address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* { **v2c** | **v3** [**authentication** | **privacy**] }

   In FIPS mode:

   snmp-agent target-host inform address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* **v3** { **authentication** | **privacy** }

   By default, no target host is configured.

   Only SNMPv2c and SNMPv3 support inform packets.

3. (Optional.) Configure a source address for sending informs.

   snmp-agent inform source *interface-type interface-number*

   By default, SNMP uses the IP address of the outgoing routed interface as the source IP address.

Configuring common parameters for sending notifications

1. Enter system view.

   system-view

2. (Optional.) Enable extended linkUp/linkDown notifications.

   snmp-agent trap if-mib link extended

By default, the SNMP agent sends standard linkUp/linkDown notifications.

If the NMS does not support extended linkUp/linkDown notifications, do not use this command.

3. (Optional.) Set the notification queue size.

   snmp-agent trap queue-size *size*

   By default, the notification queue can hold 100 notification messages.

4. (Optional.) Set the notification lifetime.

   snmp-agent trap life *seconds*

   The default notification lifetime is 120 seconds.

Examining the system configuration for changes

About this task

The SNMP module examines the system running configuration, startup configuration, and next-startup configuration file for changes periodically and generates a log if any change is found. If SNMP notifications for configuration changes has been enabled, the system generates also an SNMP notification.

Procedure

1. Enter system view.

   system-view

2. Set the interval at which the SNMP module examines the system configuration for changes.

   snmp-agent configuration-examine interval *interval*

   By default, the SNMP module examines the system configuration for changes at intervals of 600 seconds.

3. Enable SNMP notifications for system configuration changes.

   snmp-agent trap enable configuration

   By default, SNMP notifications is enabled for system configuration changes.

Configuring SNMP logging

About this task

The SNMP agent logs Get requests, Set requests, Set responses, SNMP notifications, and SNMP authentication failures, but does not log Get responses.

- **Get operation**—The agent logs the IP address of the NMS, name of the accessed node, and node OID.
- **Set operation**—The agent logs the NMS' IP address, name of accessed node, node OID, variable value, and error code and index for the Set operation.
- **Notification tracking**—The agent logs the SNMP notifications after sending them to the NMS.
- **SNMP authentication failure**—The agent logs related information when an NMS fails to be authenticated by the agent.

The SNMP module sends these logs to the information center. You can configure the information center to output these messages to certain destinations, such as the console and the log buffer. The total output size for the node field (MIB node name) and the value field (value of the MIB node) in each log entry is 1024 bytes. If this limit is exceeded, the information center truncates the data in the fields. For more information about the information center, see "Configuring the information center."

Restrictions and guidelines

Enable SNMP logging only if necessary. SNMP logging is memory-intensive and might impact device performance.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP logging.
   snmp-agent log { **all** | **authfail** | **get-operation** | **set-operation** }
   By default, SNMP logging is enabled for set operations and disabled for SNMP authentication failures and get operations.
3. Enable SNMP notification logging.
   snmp-agent trap log
   By default, SNMP notification logging is disabled.

Display and maintenance commands for SNMP

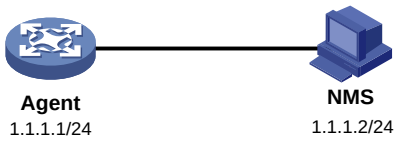
Execute **display** commands in any view.

Task	Command
Display SNMPv1 or SNMPv2c community information. (This command is not supported in FIPS mode.)	**display snmp-agent community** [**read** | **write**]
Display SNMP contexts.	**display snmp-agent context** [*context-name*]
Display SNMP group information.	**display snmp-agent group** [*group-name*]
Display the local engine ID.	**display snmp-agent local-engineid**
Display SNMP MIB node information.	**display snmp-agent mib-node** [**details** | **index-node** | **trap-node** | **verbose**]
Display MIB view information.	**display snmp-agent mib-view** [**exclude** | **include** | **viewname** *view-name*]
Display remote engine IDs.	**display snmp-agent remote** [{ *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]]
Display SNMP agent statistics.	**display snmp-agent statistics**
Display SNMP agent system information.	**display snmp-agent sys-info** [**contact** | **location** | **version**] *
Display basic information about the notification queue.	**display snmp-agent trap queue**
Display the SNMP notifications enabling status for modules.	**display snmp-agent trap-list**

Task	Command
Display SNMPv3 user information.	**display snmp-agent usm-user** [**engineid** *engineid* | **username** *user-name* | **group** *group-name*] *

SNMP configuration examples

Example: Configuring SNMPv1/SNMPv2c



The device does not support this configuration example in FIPS mode.

The configuration procedure is the same for SNMPv1 and SNMPv2c. This example uses SNMPv1.

Network configuration

As shown in Figure 4, the NMS (1.1.1.2/24) uses SNMPv1 to manage the SNMP agent (1.1.1.1/24), and the agent automatically sends notifications to report events to the NMS.

Figure 4 Network diagram

Procedure

1. Configure the SNMP agent:

   # Assign IP address **1.1.1.1/24** to the agent and make sure the agent and the NMS can reach each other. (Details not shown.)

   # Specify SNMPv1, and create read-only community **public** and read and write community **private**.

   ```
   <Agent> system-view
   [Agent] snmp-agent sys-info version v1
   [Agent] snmp-agent community read public
   [Agent] snmp-agent community write private
   ```

   # Configure contact and physical location information for the agent.

   ```
   [Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
   [Agent] snmp-agent sys-info location telephone-closet,3rd-floor
   ```

   # Enable SNMP notifications, specify the NMS at 1.1.1.2 as an SNMP trap destination, and use **public** as the community name. (To make sure the NMS can receive traps, specify the same SNMP version in the **snmp-agent target-host** command as is configured on the NMS.)

   ```
   [Agent] snmp-agent trap enable
   [Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname
   public v1
   ```

2. Configure the SNMP NMS:
   - Specify SNMPv1.
   - Create read-only community **public**, and create read and write community **private**.
   - Set the timeout timer and maximum number of retries as needed.

   For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

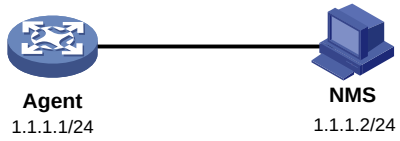
Verifying the configuration

Try to get the MTU value of the NULL0 interface from the agent. The attempt succeeds.

```
Send request to 1.1.1.1/161 ...
Protocol version: SNMPv1
Operation: Get
Request binding:
1: 1.3.6.1.2.1.2.2.1.4.135471
Response binding:
1: Oid=ifMtu.135471 Syntax=INT Value=1500
Get finished
```

Use a wrong community name to get the value of a MIB node on the agent. You can see an authentication failure trap on the NMS.

```
1.1.1.1/2934 V1 Trap = authenticationFailure
SNMP Version = V1
Community = public
Command = Trap
Enterprise = 1.3.6.1.4.1.43.1.16.4.3.50
GenericID = 4
SpecificID = 0
Time Stamp = 8:35:25.68
```



Example: Configuring SNMPv3

Network configuration

As shown in Figure 5, the NMS (1.1.1.2/24) uses SNMPv3 to monitor and manage the agent (1.1.1.1/24). The agent automatically sends notifications to report events to the NMS. The default UDP port 162 is used for SNMP notifications.

The NMS and the agent perform authentication when they establish an SNMP session. The authentication algorithm is **SHA-1** and the authentication key is **123456TESTauth&!**. The NMS and the agent also encrypt the SNMP packets between them by using the **AES** algorithm and encryption key **123456TESTencr&!**.

Figure 5 Network diagram

Configuring SNMPv3 in RBAC mode

1. Configure the agent:

   # Assign IP address **1.1.1.1/24** to the agent and make sure the agent and the NMS can reach each other. (Details not shown.)

   #Create user role **test**, and assign **test** read-only access to the objects under the **snmpMIB** node (OID:1.3.6.1.6.3.1), including the **linkUp** and **linkDown** objects.

   ```
   <Agent> system-view
   ```

```
[Agent] role name test
[Agent-role-test] rule 1 permit read oid 1.3.6.1.6.3.1
```

Assign user role **test** read-only access to the **system** node (OID:1.3.6.1.2.1.1) and read-write access to the **interfaces** node(OID:1.3.6.1.2.1.2).

```
[Agent-role-test] rule 2 permit read oid 1.3.6.1.2.1.1
[Agent-role-test] rule 3 permit read write oid 1.3.6.1.2.1.2
[Agent-role-test] quit
```

Create SNMPv3 user **RBACtest**. Assign user role **test** to **RBACtest.** Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.

```
[Agent] snmp-agent usm-user v3 RBACtest user-role test simple authentication-mode sha
123456TESTauth&! privacy-mode aes128 123456TESTencr&!
```

#Configure contact and physical location information for the agent.

```
[Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
[Agent] snmp-agent sys-info location telephone-closet,3rd-floor
```

#Enable notifications on the agent. Specify the NMS at 1.1.1.2 as the notification destination, and **RBACtest** as the username.

```
[Agent] snmp-agent trap enable
[Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params
securitynameRBACtest v3 privacy
```

2. Configure the NMS:

- Specify SNMPv3.
- Create SNMPv3 user **RBACtest**.
- Enable authentication and encryption. Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.
- Set the timeout timer and maximum number of retries.

For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

Configuring SNMPv3 in VACM mode

1. Configure the agent:

Assign IP address 1.1.1.1/24 to the agent, and make sure the agent and the NMS can reach each other. (Details not shown.)

Create SNMPv3 group **managev3group** and assign **managev3group** read-only access to the objects under the **snmpMIB** node (OID: 1.3.6.1.2.1.2.2) in the **test** view, including the **linkUp** and **linkDown** objects.

```
<Agent> system-view
[Agent] undo snmp-agent mib-view ViewDefault
[Agent] snmp-agent mib-view included test snmpMIB
[Agent] snmp-agent group v3 managev3group privacy read-view test
```

#Assign SNMPv3 group **managev3group** read-write access to the objects under the **system** node (OID: 1.3.6.1.2.1.1) and **interfaces** node (OID:1.3.6.1.2.1.2) in the **test** view.

```
[Agent] snmp-agent mib-view included test 1.3.6.1.2.1.1
[Agent] snmp-agent mib-view included test 1.3.6.1.2.1.2
[Agent] snmp-agent group v3 managev3group privacy read-view test write-view test
```

Add user **VACMtest** to SNMPv3 group **managev3group**, and set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.

```
[Agent] snmp-agent usm-user v3 VACMtest managev3group simple authentication-mode sha 123456TESTauth&! privacy-mode aes128 123456TESTencr&!
```

Configure contact and physical location information for the agent.

```
[Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
[Agent] snmp-agent sys-info location telephone-closet,3rd-floor
```

Enable notifications on the agent. Specify the NMS at 1.1.1.2 as the trap destination, and **VACMtest** as the username.

```
[Agent] snmp-agent trap enable
[Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params VACMtest v3 privacy
```

2. Configure the SNMP NMS:
   - Specify SNMPv3.
   - Create SNMPv3 user VACMtest.
   - Enable authentication and encryption. Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.
   - Set the timeout timer and maximum number of retries.

   For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

Verifying the configuration

- Use username **RBACtest** to access the agent.

  # Retrieve the value of the **sysName** node. The value **Agent** is returned.

  # Set the value for the **sysName** node to **Sysname**. The operation fails because the NMS does not have write access to the node.

  # Shut down or bring up an interface on the agent. The NMS receives linkUP (OID: 1.3.6.1.6.3.1.1.5.4) or linkDown (OID: 1.3.6.1.6.3.1.1.5.3) notifications.

- Use username **VACMtest** to access the agent.

  # Retrieve the value of the **sysName** node. The value **Agent** is returned.

  # Set the value for the **sysName** node to **Sysname**. The operation succeeds.

  # Shut down or bring up an interface on the agent. The NMS receives **linkUP** (OID: 1.3.6.1.6.3.1.1.5.4) or **linkDown** (OID: 1.3.6.1.6.3.1.1.5.3) notifications.

Configuring RMON

About RMON

Remote Network Monitoring (RMON) is an SNMP-based network management protocol. It enables proactive remote monitoring and management of network devices.

RMON working mechanism

RMON can periodically or continuously collect traffic statistics for an Ethernet port and monitor the values of MIB objects on a device. When a value reaches the threshold, the device automatically logs the event or sends a notification to the NMS. The NMS does not need to constantly poll MIB variables and compare the results.

RMON uses SNMP notifications to notify NMSs of various alarm conditions. SNMP reports function and interface operating status changes such as link up, link down, and module failure to the NMS.

RMON groups

Among standard RMON groups, the device implements the statistics group, history group, event group, alarm group, probe configuration group, and user history group. The Comware system also implements a private alarm group, which enhances the standard alarm group. The probe configuration group and user history group are not configurable from the CLI. To configure these two groups, you must access the MIB.

Statistics group

The statistics group samples traffic statistics for monitored Ethernet interfaces and stores the statistics in the Ethernet statistics table (ethernetStatsTable). The statistics include:

- Number of collisions.
- CRC alignment errors.
- Number of undersize or oversize packets.
- Number of broadcasts.
- Number of multicasts.
- Number of bytes received.
- Number of packets received.

The statistics in the Ethernet statistics table are cumulative sums.

History group

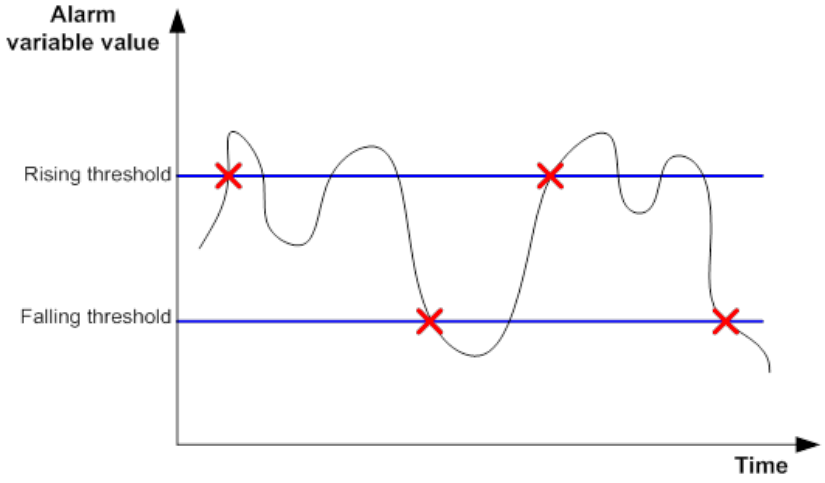
The history group periodically samples traffic statistics on interfaces and saves the history samples in the history table (etherHistoryTable). The statistics include:

- Bandwidth utilization.
- Number of error packets.
- Total number of packets.

The history table stores traffic statistics collected for each sampling interval.

Event group

The event group controls the generation and notifications of events triggered by the alarms defined in the alarm group and the private alarm group. The following are RMON alarm event handling methods:



- **Log**—Logs event information (including event time and description) in the event log table so the management device can get the logs through SNMP.
- **Trap**—Sends an SNMP notification when the event occurs.
- **Log-Trap**—Logs event information in the event log table and sends an SNMP notification when the event occurs.
- **None**—Takes no actions.

Alarm group

The RMON alarm group monitors alarm variables, such as the count of incoming packets (etherStatsPkts) on an interface. After you create an alarm entry, the RMON agent samples the value of the monitored alarm variable regularly. If the value of the monitored variable is greater than or equal to the rising threshold, a rising alarm event is triggered. If the value of the monitored variable is smaller than or equal to the falling threshold, a falling alarm event is triggered. The event group defines the action to take on the alarm event.

If an alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in Figure 1.

Figure 1 Rising and falling alarm events

Private alarm group

The private alarm group enables you to perform basic math operations on multiple variables, and compare the calculation result with the rising and falling thresholds.

The RMON agent samples variables and takes an alarm action based on a private alarm entry as follows:

1. Samples the private alarm variables in the user-defined formula.
2. Processes the sampled values with the formula.
3. Compares the calculation result with the predefined thresholds, and then takes one of the following actions:
   - Triggers the event associated with the rising alarm event if the result is equal to or greater than the rising threshold.
   - Triggers the event associated with the falling alarm event if the result is equal to or less than the falling threshold.

If a private alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable

crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event.

Sample types for the alarm group and the private alarm group

The RMON agent supports the following sample types:

- **absolute**—RMON compares the value of the monitored variable with the rising and falling thresholds at the end of the sampling interval.
- **delta**—RMON subtracts the value of the monitored variable at the previous sample from the current value, and then compares the difference with the rising and falling thresholds.

Protocols and standards

- RFC 4502, *Remote Network Monitoring Management Information Base Version 2*
- RFC 2819, *Remote Network Monitoring Management Information Base Status of this Memo*

Configuring the RMON statistics function

About the RMON statistics function

RMON implements the statistics function through the Ethernet statistics group and the history group.

The Ethernet statistics group provides the cumulative statistic for a variable from the time the statistics entry is created to the current time.

The history group provides statistics that are sampled for a variable for each sampling interval. The history group uses the history control table to control sampling, and it stores samples in the history table.

Creating an RMON Ethernet statistics entry

Restrictions and guidelines

The index of an RMON statistics entry must be globally unique. If the index has been used by another interface, the creation operation fails.

You can create only one RMON statistics entry for an Ethernet interface.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Create an RMON Ethernet statistics entry.
   rmon statistics *entry-number* [**owner** *text*]

Creating an RMON history control entry

Restrictions and guidelines

You can configure multiple history control entries for one interface, but you must make sure their entry numbers and sampling intervals are different.

You can create a history control entry successfully even if the specified bucket size exceeds the available history table size. RMON will set the bucket size as closely to the expected bucket size as possible.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Create an RMON history control entry.

   rmon history *entry-number* **buckets** *number* **interval** *interval* [**owner** *text*]

   By default, no RMON history control entries exist.

   You can create multiple RMON history control entries for an Ethernet interface.

Configuring the RMON alarm function

Restrictions and guidelines

When you create a new event, alarm, or private alarm entry, follow these restrictions and guidelines:

- The entry must not have the same set of parameters as an existing entry.
- The maximum number of entries is not reached.

Table 1 shows the parameters to be compared for duplication and the entry limits.

Table 1 RMON configuration restrictions

Entry	Parameters to be compared	Maximum number of entries
Event	• Event description (**description** *string*) • Event type (**log**, **trap**, **logtrap**, or **none**) • Community name (*security-string*)	60
Alarm	• Alarm variable (*alarm-variable*) • Sampling interval (*sampling-interval*) • Sample type (**absolute** or **delta**) • Rising threshold (*threshold-value1*) • Falling threshold (*threshold-value2*)	60
Private alarm	• Alarm variable formula (*prialarm-formula*) • Sampling interval (*sampling-interval*) • Sample type (**absolute** or **delta**) • Rising threshold (*threshold-value1*) • Falling threshold (*threshold-value2*)	50

Prerequisites

To send notifications to the NMS when an alarm is triggered, configure the SNMP agent as described in "Configuring SNMP" before configuring the RMON alarm function.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Create an RMON event entry.

   rmon event *entry-number* [**description** *string*] { **log** | **log-trap** *security-string* | **none** | **trap** *security-string* } [**owner** *text*]

   By default, no RMON event entries exist.

3. Create an RMON alarm entry.

   - Create an RMON alarm entry.

     rmon alarm *entry-number alarm-variable sampling-interval* { **absolute** | **delta** } [**startup-alarm** { **falling** | **rising** | **rising-falling** }] **rising-threshold** *threshold-value1 event-entry1* **falling-threshold** *threshold-value2 event-entry2* [**owner** *text*]

   - Create an RMON private alarm entry.

     rmon prialarm *entry-number prialarm-formula prialarm-des sampling-interval* { **absolute** | **delta** } [**startup-alarm** { **falling** | **rising** | **rising-falling** }] **rising-threshold** *threshold-value1 event-entry1* **falling-threshold** *threshold-value2 event-entry2* **entrytype** { **forever** | **cycle** *cycle-period* } [**owner** *text*]

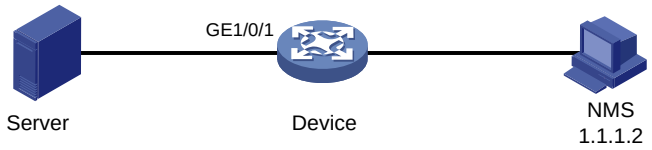
   By default, no RMON alarm entries or RMON private alarm entries exist.

   You can associate an alarm with an event that has not been created yet. The alarm will trigger the event only after the event is created.

Display and maintenance commands for RMON

Execute **display** commands in any view.

Task	Command
Display RMON alarm entries.	**display rmon alarm** [*entry-number*]
Display RMON event entries.	**display rmon event** [*entry-number*]
Display log information for event entries.	**display rmon eventlog** [*entry-number*]
Display RMON history control entries and history samples.	**display rmon history** [*interface-type interface-number*]
Display RMON private alarm entries.	**display rmon prialarm** [*entry-number*]
Display RMON statistics.	**display rmon statistics** [*interface-type interface-number*]



RMON configuration examples

Example: Configuring the Ethernet statistics function

Network configuration

As shown in Figure 2, create an RMON Ethernet statistics entry on the device to gather cumulative traffic statistics for GigabitEthernet 1/0/1.

Figure 2 Network diagram

Procedure

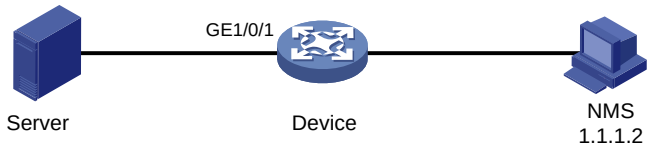
Create an RMON Ethernet statistics entry for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon statistics 1 owner user1
```

Verifying the configuration

Display statistics collected for GigabitEthernet 1/0/1.

```
<Sysname> display rmon statistics gigabitethernet 1/0/1
EtherStatsEntry 1 owned by user1 is VALID.
  Interface : GigabitEthernet1/0/1<ifIndex.3>
  etherStatsOctets         : 21657     , etherStatsPkts          : 307
  etherStatsBroadcastPkts  : 56        , etherStatsMulticastPkts : 34
  etherStatsUndersizePkts  : 0         , etherStatsOversizePkts  : 0
  etherStatsFragments      : 0         , etherStatsJabbers       : 0
  etherStatsCRCAlignErrors : 0         , etherStatsCollisions    : 0
  etherStatsDropEvents (insufficient resources): 0
  Incoming packets by size:
  64     : 235       ,  65-127  : 67        ,  128-255  : 4
  256-511: 1         ,  512-1023: 0         ,  1024-1518: 0
```



Get the traffic statistics from the NMS through SNMP. (Details not shown.)

Example: Configuring the history statistics function

Network configuration

As shown in Figure 3, create an RMON history control entry on the device to sample traffic statistics for GigabitEthernet 1/0/1 every minute.

Figure 3 Network diagram

Procedure

Create an RMON history control entry to sample traffic statistics every minute for GigabitEthernet 1/0/1. Retain a maximum of eight samples for the interface in the history statistics table.

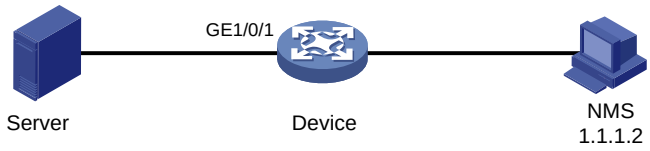
```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon history 1 buckets 8 interval 60 owner user1
```

Verifying the configuration

Display the history statistics collected for GigabitEthernet 1/0/1.

```
[Sysname-GigabitEthernet1/0/1] display rmon history
HistoryControlEntry 1 owned by user1 is VALID
  Sampled interface     : GigabitEthernet1/0/1<ifIndex.3>
  Sampling interval     : 60(sec) with 8 buckets max
  Sampling record 1 :
    dropevents        : 0         , octets               : 834
    packets           : 8         , broadcast packets    : 1
    multicast packets : 6         , CRC alignment errors : 0
    undersize packets : 0         , oversize packets     : 0
    fragments         : 0         , jabbers              : 0
    collisions        : 0         , utilization          : 0
  Sampling record 2 :
    dropevents        : 0         , octets               : 962
    packets           : 10        , broadcast packets    : 3
    multicast packets : 6         , CRC alignment errors : 0
    undersize packets : 0         , oversize packets     : 0
    fragments         : 0         , jabbers              : 0
    collisions        : 0         , utilization          : 0
```

Get the traffic statistics from the NMS through SNMP. (Details not shown.)



Example: Configuring the alarm function

Network configuration

As shown in Figure 4, configure the device to monitor the incoming traffic statistic on GigabitEthernet 1/0/1, and send RMON alarms when either of the following conditions is met:

- The 5-second delta sample for the traffic statistic crosses the rising threshold (100).
- The 5-second delta sample for the traffic statistic drops below the falling threshold (50).

Figure 4 Network diagram

Procedure

Configure the SNMP agent (the device) with the same SNMP settings as the NMS at 1.1.1.2. This example uses SNMPv1, read community **public**, and write community **private**.

```
<Sysname> system-view
[Sysname] snmp-agent
[Sysname] snmp-agent community read public
[Sysname] snmp-agent community write private
[Sysname] snmp-agent sys-info version v1
[Sysname] snmp-agent trap enable
[Sysname] snmp-agent trap log
[Sysname] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname
public
```

Create an RMON Ethernet statistics entry for GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon statistics 1 owner user1
[Sysname-GigabitEthernet1/0/1] quit
```

Create an RMON event entry and an RMON alarm entry to send SNMP notifications when the delta sample for 1.3.6.1.2.1.16.1.1.1.4.1 exceeds 100 or drops below 50.

```
[Sysname] rmon event 1 trap public owner user1
[Sysname] rmon alarm 1 1.3.6.1.2.1.16.1.1.1.4.1 5 delta rising-threshold 100 1
falling-threshold 50 1 owner user1
```

NOTE:

The string 1.3.6.1.2.1.16.1.1.1.4.1 is the object instance for GigabitEthernet 1/0/1. The digits before the last digit (1.3.6.1.2.1.16.1.1.1.4) represent the object for total incoming traffic statistics. The last digit (1) is the RMON Ethernet statistics entry index for GigabitEthernet 1/0/1.

Verifying the configuration

Display the RMON alarm entry.

```
<Sysname> display rmon alarm 1
AlarmEntry 1 owned by user1 is VALID.
  Sample type                    : delta
  Sampled variable               : 1.3.6.1.2.1.16.1.1.1.4.1<etherStatsOctets.1>
  Sampling interval (in seconds) : 5
  Rising threshold               : 100(associated with event 1)
  Falling threshold              : 50(associated with event 1)
  Alarm sent upon entry startup  : risingOrFallingAlarm
  Latest value                   : 0
```

Display statistics for GigabitEthernet 1/0/1.

```
<Sysname> display rmon statistics gigabitethernet 1/0/1
EtherStatsEntry 1 owned by user1 is VALID.
```

```
Interface : GigabitEthernet1/0/1<ifIndex.3>
etherStatsOctets         : 57329     , etherStatsPkts          : 455
etherStatsBroadcastPkts  : 53        , etherStatsMulticastPkts : 353
etherStatsUndersizePkts  : 0         , etherStatsOversizePkts  : 0
etherStatsFragments      : 0         , etherStatsJabbers       : 0
etherStatsCRCAlignErrors : 0         , etherStatsCollisions    : 0
etherStatsDropEvents (insufficient resources): 0
Incoming packets by size :
64     : 7         ,  65-127  : 413       ,  128-255  : 35
256-511: 0         ,  512-1023: 0         ,  1024-1518: 0
```

The NMS receives the notification when the alarm is triggered.

Configuring the Event MIB

About the Event MIB

The Event Management Information Base (Event MIB) is an SNMPv3-based network management protocol and is an enhancement to remote network monitoring (RMON). The Event MIB uses Boolean tests, existence tests, and threshold tests to monitor MIB objects on a local or remote system. It triggers the predefined notification or set action when a monitored object meets the trigger condition.

Trigger

The Event MIB uses triggers to manage and associate the three elements of the Event MIB: monitored object, trigger condition, and action.

Monitored objects

The Event MIB can monitor the following MIB objects:

- Table node.
- Conceptual row node.
- Table column node.
- Simple leaf node.
- Parent node of a leaf node.

To monitor a single MIB object, specify it by its OID or name. To monitor a set of MIB objects, specify the common OID or name of the group and enable wildcard matching. For example, specify ifDescr.2 to monitor the description for the interface with index 2. Specify ifDescr and enable wildcard matching to monitor the descriptions for all interfaces.

Trigger test

A trigger supports Boolean, existence, and threshold tests.

Boolean test

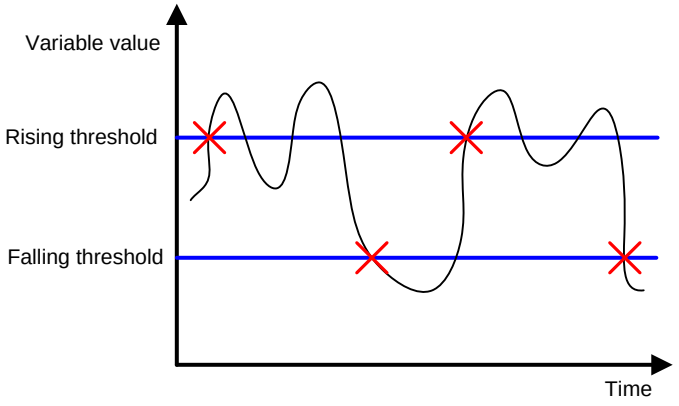
A Boolean test compares the value of the monitored object with the reference value and takes actions according to the comparison result. The comparison types include **unequal**, **equal**, **less**, **lessorequal**, **greater**, and **greaterorequal**. For example, if the comparison type is **equal**, an event is triggered when the value of the monitored object equals the reference value. The event will not be triggered again until the value becomes unequal and comes back to equal.

Existence test

An existence test monitors and manages the absence, presence, and change of a MIB object, for example, interface status. When a monitored object is specified, the system reads the value of the monitored object regularly.

- If the test type is **Absent**, the system triggers an alarm event and takes the specified action when the state of the monitored object changes to absent.
- If the test type is **Present**, the system triggers an alarm event and takes the specified action when the state of the monitored object changes to present.
- If the test type is **Changed**, the system triggers an alarm event and takes the specified action when the value of the monitored object changes.

Threshold test



A threshold test regularly compares the value of the monitored object with the threshold values.

- A rising alarm event is triggered if the value of the monitored object is greater than or equal to the rising threshold.
- A falling alarm event is triggered if the value of the monitored object is smaller than or equal to the falling threshold.
- A rising alarm event is triggered if the difference between the current sampled value and the previous sampled value is greater than or equal to the delta rising threshold.
- A falling alarm event is triggered if the difference between the current sampled value and the previous sampled value is smaller than or equal to the delta falling threshold.
- A falling alarm event is triggered if the values of the monitored object, the rising threshold, and the falling threshold are the same.
- A falling alarm event is triggered if the delta rising threshold, the delta falling threshold, and the difference between the current sampled value and the previous sampled value is the same.

The alarm management module defines the set or notification action to take on alarm events.

If the value of the monitored object crosses a threshold multiple times in succession, the managed device triggers an alarm event only for the first crossing. For example, if the value of a sampled object crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in Figure 1.

Figure 1 Rising and falling alarm events

Event actions

The Event MIB triggers one or both of the following actions when the trigger condition is met:

- **Set action**—Uses SNMP to set the value of the monitored object.
- **Notification action**—Uses SNMP to send a notification to the NMS. If an object list is specified for the notification action, the notification will carry the specified objects in the object list.

Object list

An object list is a set of MIB objects. You can specify an object list in trigger view, trigger-test view (including trigger-Boolean view, trigger existence view, and trigger threshold view), and action-notification view. If a notification action is triggered, the device sends a notification carrying the object list to the NMS.

If you specify an object list respectively in any two of the views or all the three views, the object lists are added to the triggered notifications in this sequence: trigger view, trigger-test view, and action-notification view.

Object owner

Trigger, event, and object list use an owner and name for unique identification. The owner must be an SNMPv3 user that has been created on the device. If you specify a notification action for a trigger, you must establish an SNMPv3 connection between the device and NMS by using the SNMPv3 username. For more information about SNMPv3 user, see "SNMP configuration".

Restrictions and guidelines: Event MIB configuration

The Event MIB and RMON are independent of each other. You can configure one or both of the features for network management.

You must specify the same owner for a trigger, object lists of the trigger, and events of the trigger.

Event MIB tasks at a glance

To configure the Event MIB, perform the following tasks:

1. Configuring the Event MIB global sampling parameters
2. (Optional.) Configuring Event MIB object lists

   Perform this task so that the device sends a notification that carries the specified object list to the NMS when a notification action is triggered.
3. Configuring an event

   The device supports set and notification actions. Choose one or two of the following actions:
   - Creating an event
   - Configuring a set action for an event
   - Configuring a notification action for an event
   - Enabling the event
4. Configuring a trigger

   A trigger supports Boolean, existence, and threshold tests. Choose one or more of the following tests:
   - Creating a trigger and configuring its basic parameters
   - Configuring a Boolean trigger test
   - Configuring an existence trigger test
   - Configuring a threshold trigger test
   - Enabling trigger sampling
5. (Optional.) Enabling SNMP notifications for the Event MIB module

Prerequisites for configuring the Event MIB

Before you configure the Event MIB, perform the following tasks:

- Create an SNMPv3 user. Assign the user the rights to read and set the values of the specified MIB objects and object lists.

- Make sure the SNMP agent and NMS are configured correctly and the SNMP agent can send notifications to the NMS correctly.

Configuring the Event MIB global sampling parameters

Restrictions and guidelines

This tasks takes effect only on monitored instances to be created.

Procedure

1. Enter system view.

   system-view
2. Set the minimum sampling interval.

   snmp mib event sample minimum *min-number*

   By default, the minimum sampling interval is 1 second.

   The sampling interval of a trigger must be greater than the minimum sampling interval.
3. Configure the maximum number of object instances that can be concurrently sampled.

   snmp mib event sample instance maximum *max-number*

   By default, the value is 0. The maximum number of object instances that can be concurrently sampled is limited by the available resources.

Configuring Event MIB object lists

About this task

Perform this task so that the device sends a notification that carries the specified objects to the NMS when a notification action is triggered.

Procedure

1. Enter system view.

   system-view
2. Configure an Event MIB object list.

   snmp mib event object list owner *group-owner* **name** *group-name* *object-index* **oid** *object-identifier* [**wildcard**]

   The object can be a table node, conceptual row node, table column node, simple leaf node, or parent node of a leaf node.

Configuring an event

Creating an event

1. Enter system view.

   system-view
2. Create an event and enter its view.

   snmp mib event owner *event-owner* **name** *event-name*
3. (Optional.) Configure a description for the event.

description *text*

By default, an event does not have a description.

Configuring a set action for an event

1. Enter system view.

   system-view
2. Enter event view.

   snmp mib event owner *event-owner* **name** *event-name*
3. Enable the set action and enter set action view.

   action set

   By default, no action is specified for an event.
4. Specify an object by its OID for the set action.

   oid *object-identifier*

   By default, no object is specified for a set action.

   The object can be a table node, conceptual row node, table column node, simple leaf node, or parent node of a leaf node.
5. Enable OID wildcarding.

   wildcard oid

   By default, OID wildcarding is disabled.
6. Set the value for the object.

   value *integer-value*

   The default value for the object is 0.
7. (Optional.) Specify a context for the object.

   context *context-name*

   By default, no context is specified for an object.
8. (Optional.) Enable context wildcarding.

   wildcard context

   By default, context wildcarding is disabled.

   A wildcard context contains the specified context and the wildcarded part.

Configuring a notification action for an event

1. Enter system view.

   system-view
2. Enter event view

   snmp mib event owner *event-owner* **name** *event-name*
3. Enable the notification action and enter notification action view.

   action notification

   By default, no action is specified for an event.
4. Specify an object to execute the notification action by its OID.

   oid *object-identifier*

   By default, no object is specified for executing the notification action.

   The object must be a notification object.
5. Specify an object list to be added to the notification triggered by the event.

object list owner *group-owner* **name** *group-name*

By default, no object list is specified for the notification action.

If you do not specify an object list for the notification action or the specified object list does not contain variables, no variables will be carried in the notification.

Enabling the event

Restrictions and guidelines

The Boolean, existence, and threshold events can be triggered only after you perform this task.

To change an enabled event, first disable the event.

Procedure

1. Enter system view.
   system-view
2. Enter event view.
   snmp mib event owner *event-owner* **name** *event-name*
3. Enable the event.
   event enable
   By default, an event is disabled.

Configuring a trigger

Creating a trigger and configuring its basic parameters

1. Enter system view.
   system-view
2. Create a trigger and enter its view.
   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*
   The trigger owner must be an existing SNMPv3 user.
3. (Optional.) Configure a description for the trigger.
   description *text*
   By default, a trigger does not have a description.
4. Set a sampling interval for the trigger.
   frequency *interval*
   By default, the sampling interval is 600 seconds.
   Make sure the sampling interval is greater than or equal to the Event MIB minimum sampling interval.
5. Specify a sampling method.
   sample { **absolute** | **delta** }
   The default sampling method is **absolute**.
6. Specify an object to be sampled by its OID.
   oid *object-identifier*
   By default, the OID is 0.0. No object is specified for a trigger.
   If you execute this command multiple times, the most recent configuration takes effect.
7. (Optional.) Enable OID wildcarding.

wildcard oid

By default, OID wildcarding is disabled.

8. (Optional.) Configure a context for the monitored object.

   context *context-name*

   By default, no context is configured for a monitored object.

9. (Optional.) Enable context wildcarding.

   wildcard context

   By default, context wildcarding is disabled.

10. (Optional.) Specify the object list to be added to the triggered notification.

    object list owner *group-owner* **name** *group-name*

    By default, no object list is specified for a trigger.

Configuring a Boolean trigger test

1. Enter system view.

   system-view

2. Enter trigger view.

   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Specify a Boolean test for the trigger and enter trigger-Boolean view.

   test boolean

   By default, no test is configured for a trigger.

4. Specify a Boolean test comparison type.

   comparison { **equal** | **greater** | **greaterorequal** | **less** | **lessorequal** | **unequal** }

   The default Boolean test comparison type is **unequal**.

5. Set a reference value for the Boolean trigger test.

   value *integer-value*

   The default reference value for a Boolean trigger test is 0.

6. Specify an event for the Boolean trigger test.

   event owner *event-owner* **name** *event-name*

   By default, no event is specified for a Boolean trigger test.

7. (Optional.) Specify the object list to be added to the notification triggered by the test.

   object list owner *group-owner* **name** *group-name*

   By default, no object list is specified for a Boolean trigger test.

8. Enable the event to be triggered when the trigger condition is met at the first sampling.

   startup enable

   By default, the event is triggered when the trigger condition is met at the first sampling.

   Before the first sampling, you must enable this command to allow the event to be triggered.

Configuring an existence trigger test

1. Enter system view.

   system-view

2. Enter trigger view.

snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Specify an existence test for the trigger and enter trigger-existence view.
   test existence
   By default ,no test is configured for a trigger.
4. Specify an event for the existence trigger test.
   event owner *event-owner* **name** *event-name*
   By default, no event is specified for an existence trigger test.
5. (Optional.) Specify the object list to be added to the notification triggered by the test.
   object list owner *group-owner* **name** *group-name*
   By default, no object list is specified for an existence trigger test.
6. Specify an existence trigger test type.
   type { **absent** | **changed** | **present** }
   The default existence trigger test types are **present** and **absent**.
7. Specify an existence trigger test type for the first sampling.
   startup { **absent** | **present** }
   By default, both the **present** and **absent** existence trigger test types are allowed for the first sampling.

Configuring a threshold trigger test

1. Enter system view.
   system-view
2. Enter trigger view.
   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*
3. Specify a threshold test for the trigger and enter trigger-threshold view.
   test boolean
   By default ,no test is configured for a trigger.
4. Specify the object list to be added to the notification triggered by the test.
   object list owner *group-owner* **name** *group-name*
   By default, no object list is specified for a threshold trigger test.
5. (Optional.) Specify the type of the threshold trigger test for the first sampling.
   startup { **falling** | **rising** | **rising-or-falling** }
   The default threshold trigger test type for the first sampling is **rising-or-falling**.
6. Specify the delta falling threshold and the falling alarm event triggered when the delta value (difference between the current sampled value and the previous sampled value) is smaller than or equal to the delta falling threshold.
   delta falling { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }
   By default, the delta falling threshold is 0, and no falling alarm event is specified.
7. Specify the delta rising threshold and the rising alarm event triggered when the delta value is greater than or equal to the delta rising threshold.
   delta rising { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }
   By default, the delta rising threshold is 0, and no rising alarm event is specified.

8. Specify the falling threshold and the falling alarm event triggered when the sampled value is smaller than or equal to the threshold.

   falling { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }

   By default, the falling threshold is 0, and no falling alarm event is specified.

9. Specify the rising threshold and the ring alarm event triggered when the sampled value is greater than or equal to the threshold.

   rising { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }

   By default, the rising threshold is 0, and no rising alarm event is specified.

Enabling trigger sampling

Restrictions and guidelines

Enable trigger sampling after you complete trigger parameters configuration. You cannot modify trigger parameters after trigger sampling is enabled. To modify trigger parameters, first disable trigger sampling.

Procedure

1. Enter system view.

   system-view

2. Enter trigger view.

   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Enable trigger sampling.

   trigger enable

   By default, trigger sampling is disabled.

Enabling SNMP notifications for the Event MIB module

About this task

To report critical Event MIB events to an NMS, enable SNMP notifications for the Event MIB module. For Event MIB event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.

   system-view

2. Enable snmp notifications for the Event MIB module.

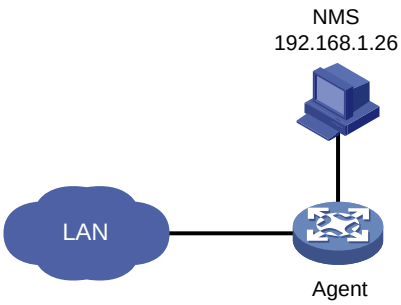
   snmp-agent trap enable event-mib

   By default, SNMP notifications are enabled for the Event MIB module.

Display and maintenance commands for Event MIB

Execute **display** commands in any view.

Task	Command
Display Event MIB configuration and statistics.	**display snmp mib event**
Display event information.	**display snmp mib event event** [**owner** *event-owner* **name** *event-name*]
Display object list information.	**display snmp mib event object list** [**owner** *group-owner* **name** *group-name*]
Display global Event MIB configuration and statistics.	**display snmp mib event summary**
Display trigger information.	**display snmp mib event trigger** [**owner** *trigger-owner* **name** *trigger-name*]



Event MIB configuration examples

Example: Configuring an existence trigger test

Network configuration

As shown in Figure 2, the device acts as the agent. Use the Event MIB to monitor the device. When interface hot-swap or virtual interface creation or deletion occurs on the device, the agent sends an mteTriggerFired notification to the NMS.

Figure 2 Network diagram

Procedure

1. Enable and configure the SNMP agent on the device:

   # Create SNMPv3 group **g3** and add SNMPv3 user **owner1** to **g3**.

   ```
   <Sysname> system-view
   [Sysname] snmp-agent usm-user v3 owner1 g3
   [Sysname] snmp-agent group v3 g3 read-view a write-view a notify-view a
   [Sysname] snmp-agent mib-view included a iso
   ```

   # Configure context **contextnameA** for the agent.

```
[Sysname] snmp-agent context contextnameA
```

Enable SNMP notifications for the Event MIB module. Specify the NMS at **192.168.1.26** as the target host for the notifications.

```
[Sysname] snmp-agent trap enable event-mib
[Sysname] snmp-agent target-host trap address udp-domain 192.168.1.26 params securityname owner1 v3
```

2. Configure the Event MIB global sampling parameters.

Set the Event MIB minimum sampling interval to 50 seconds.

```
[Sysname] snmp mib event sample minimum 50
```

Set the maximum number to 100 for object instances that can be concurrently sampled.

```
[Sysname] snmp mib event sample instance maximum 100
```

3. Create and configure a trigger:

Create a trigger and enter its view. Specify its owner as **owner1** and its name as **triggerA**.

```
[Sysname] snmp mib event trigger owner owner1 name triggerA
```

Set the sampling interval to 60 seconds. Make sure the sampling interval is greater than or equal to the Event MIB minimum sampling interval.

```
[Sysname-trigger-owner1-triggerA] frequency 60
```

Specify object OID **1.3.6.1.2.1.2.2.1.1** as the monitored object. Enable OID wildcarding.

```
[Sysname-trigger-owner1-triggerA] oid 1.3.6.1.2.1.2.2.1.1
[Sysname-trigger-owner1-triggerA] wildcard oid
```

Configure context **contextnameA** for the monitored object and enable context wildcarding.

```
[Sysname-trigger-owner1-triggerA] context contextnameA
[Sysname-trigger-owner1-triggerA] wildcard context
```

Specify the existence trigger test for the trigger.

```
[Sysname-trigger-owner1-triggerA] test existence
[Sysname-trigger-owner1-triggerA-existence] quit
```

Enable trigger sampling.

```
[Sysname-trigger-owner1-triggerA] trigger enable
[Sysname-trigger-owner1-triggerA] quit
```

Verifying the configuration

Display Event MIB brief information.

```
[Sysname] display snmp mib event summary
TriggerFailures               : 0
EventFailures                 : 0
SampleMinimum                 : 50
SampleInstanceMaximum         : 100
SampleInstance                : 20
SampleInstancesHigh           : 20
SampleInstanceLacks           : 0
```

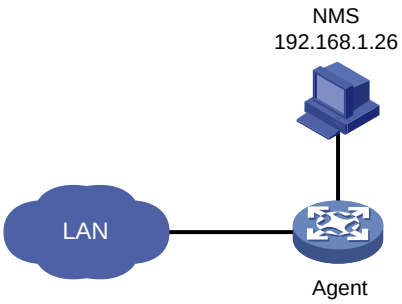
Display information about the trigger with owner **owner1** and name **trigger A**.

```
[Sysname] display snmp mib event trigger owner owner1 name triggerA
Trigger entry triggerA owned by owner1:
  TriggerComment              : N/A
  TriggerTest                 : existence
  TriggerSampleType           : absoluteValue
  TriggerValueID              : 1.3.6.1.2.1.2.2.1.1<ifIndex>
  TriggerValueIDWildcard      : true
```

```
  TriggerTargetTag            : N/A
  TriggerContextName          : contextnameA
  TriggerContextNameWildcard  : true
  TriggerFrequency(in seconds): 60
  TriggerObjOwner             : N/A
  TriggerObjName              : N/A
  TriggerEnabled              : true
  Existence entry:
   ExiTest                    : present | absent
   ExiStartUp                 : present | absent
   ExiObjOwner                : N/A
   ExiObjName                 : N/A
   ExiEvtOwner                : N/A
   ExiEvtName                 : N/A
```

Create VLAN-interface 2 on the device.

```
[Sysname] vlan 2
[Sysname-vlan2] quit
[Sysname] interface vlan 2
```



The NMS receives an mteTriggerFired notification from the device.

Example: Configuring a Boolean trigger test

Network configuration

As shown in Figure 2, the device acts as the agent. The NMS uses SNMPv3 to monitor and manage the device. Configure a trigger and configure a Boolean trigger test for the trigger. When the trigger condition is met, the agent sends an mteTriggerFired notification to the NMS.

Figure 3 Network diagram

Procedure

1. Enable and configure the SNMP agent on the device:

   # Create SNMPv3 group **g3** and add SNNPv3 user **owner1** to **g3**.

   ```
   <Sysname> system-view
   [Sysname] snmp-agent usm-user v3 owner1 g3
   [Sysname] snmp-agent group v3 g3 read-view a write-view a notify-view a
   [Sysname] snmp-agent mib-view included a iso
   ```

   # Enable SNMP notifications for the Event MIB module. Specify the NMS at **192.168.1.26** as the target host for the notifications.

   ```
   [Sysname] snmp-agent trap enable event-mib
   ```

```
[Sysname] snmp-agent target-host trap address udp-domain 192.168.1.26 params
securityname owner1 v3
```

2. Configure the Event MIB global sampling parameters.

Set the Event MIB minimum sampling interval to 50 seconds.

```
[Sysname] snmp mib event sample minimum 50
```

Set the maximum number to 100 for object instances that can be concurrently sampled.

```
[Sysname] snmp mib event sample instance maximum 100
```

3. Configure Event MIB object lists **objectA**, **objectB**, and **objectC**.

```
[Sysname] snmp mib event object list owner owner1 name objectA 1 oid
1.3.6.1.4.1.25506.2.6.1.1.1.1.6.11
[Sysname] snmp mib event object list owner owner1 name objectB 1 oid
1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11
[Sysname] snmp mib event object list owner owner1 name objectC 1 oid
1.3.6.1.4.1.25506.2.6.1.1.1.1.8.11
```

4. Configure an event:

Create an event and enter its view. Specify its owner as **owner1** and its name as **EventA**.

```
[Sysname] snmp mib event owner owner1 name EventA
```

Specify the notification action for the event. Specify object OID **1.3.6.1.4.1.25506.2.6.2.0.5 (hh3cEntityExtMemUsageThresholdNotification)** to execute the notification.

```
[Sysname-event-owner1-EventA] action notification
[Sysname-event-owner1-EventA-notification] oid 1.3.6.1.4.1.25506.2.6.2.0.5
```

Specify the object list with owner **owner 1** and name **objectC** to be added to the notification when the notification action is triggered

```
[Sysname-event-owner1-EventA-notification] object list owner owner1 name objectC
[Sysname-event-owner1-EventA-notification] quit
```

Enable the event.

```
[Sysname-event-owner1-EventA] event enable
[Sysname-event-owner1-EventA] quit
```

5. Configure a trigger:

Create a trigger and enter its view. Specify its owner as **owner1** and its name as **triggerA**.

```
[Sysname] snmp mib event trigger owner owner1 name triggerA
```

Set the sampling interval to 60 seconds. Make sure the interval is greater than or equal to the global minimum sampling interval.

```
[Sysname-trigger-owner1-triggerA] frequency 60
```

Specify object OID **1.3.6.1.4.1.25506.2.6.1.1.1.1.9.11** as the monitored object.

```
[Sysname-trigger-owner1-triggerA] oid 1.3.6.1.4.1.25506.2.6.1.1.1.1.9.11
```

Specify the object list with owner **owner1** and name **objectA** to be added to the notification when the notification action is triggered.

```
[Sysname-trigger-owner1-triggerA] object list owner owner1 name objectA
```

Configure a Boolean trigger test. Set its comparison type to greater, reference value to 10, and specify the event with owner **owner1** and name **EventA**, object list with owner **owner1** and name **objectB** for the test.

```
[Sysname-trigger-owner1-triggerA] test boolean
[Sysname-trigger-owner1-triggerA-boolean] comparison greater
[Sysname-trigger-owner1-triggerA-boolean] value 10
[Sysname-trigger-owner1-triggerA-boolean] event owner owner1 name EventA
[Sysname-trigger-owner1-triggerA-boolean] object list owner owner1 name objectB
[Sysname-trigger-owner1-triggerA-boolean] quit
```

Enable trigger sampling.

```
[Sysname-trigger-owner1-triggerA] trigger enable
[Sysname-trigger-owner1-triggerA] quit
```

Verifying the configuration

Display Event MIB configuration and statistics.

```
[Sysname] display snmp mib event summary
TriggerFailures              : 0
EventFailures                : 0
SampleMinimum                : 50
SampleInstanceMaximum        : 10
SampleInstance               : 1
SampleInstancesHigh          : 1
SampleInstanceLacks          : 0
```

Display information about the Event MIB object lists.

```
[Sysname] display snmp mib event object list
Object list objectA owned by owner1:
  ObjIndex                   : 1
  ObjID                      : 1.3.6.1.4.1.25506.2.6.1.1.1.1.6.11<hh3cEntityExt

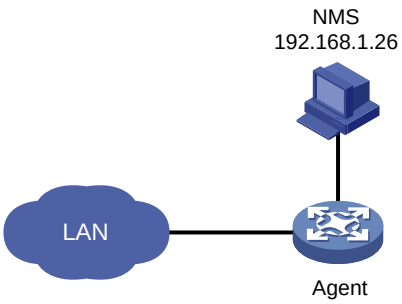
  TriggerValueIDWildcard      : false
  TriggerTargetTag            : N/A
  TriggerContextName          : N/A
  TriggerContextNameWildcard  : false
  TriggerFrequency(in seconds): 60
  TriggerObjOwner             : owner1
  TriggerObjName              : objectA
  TriggerEnabled              : true
  Boolean entry:
   BoolCmp                    : greater
   BoolValue                  : 10
   BoolStartUp                : true
   BoolObjOwner               : owner1
   BoolObjName                : objectB
   BoolEvtOwner               : owner1
   BoolEvtName                : EventA
```



When the value of the monitored object 1.3.6.1.4.1.25506.2.6.1.1.1.1.9.11 becomes greater than 10, the NMS receives an mteTriggerFired notification.

Example: Configuring a threshold trigger test

Network configuration

As shown in Figure 2, the device acts as the agent. The NMS uses SNMPv3 to monitor and manage the device. Configure a trigger and configure a threshold trigger test for the trigger. When the trigger conditions are met, the agent sent an mteTriggerFired notification to the NMS.

Figure 4 Network diagram

Procedure

1. Enable and configure the SNMP agent on the device:

   # Create SNMPv3 group **g3** and add SNMPv3 user **owner1** to **g3**.

   ```
   <Sysname> system-view
   [Sysname] snmp-agent usm-user v3 owner1 g3
   [Sysname] snmp-agent group v3 g3 read-view a write-view a notify-view a
   [Sysname] snmp-agent mib-view included a iso
   ```

   # Enable SNMP notifications for the Event MIB module. Specify the NMS at **192.168.1.26** as the target host for the notifications.

   ```
   [Sysname] snmp-agent trap enable event-mib
   ```

```
[Sysname] snmp-agent target-host trap address udp-domain 192.168.1.26 params
securityname owner1 v3
[Sysname] snmp-agent trap enable
```

2. Configure the Event MIB global sampling parameters.

   # Set the Event MIB minimum sampling interval to 50 seconds.

   ```
   [Sysname] snmp mib event sample minimum 50
   ```

   # Set the maximum number to 10 for object instances that can be concurrently sampled.

   ```
   [Sysname] snmp mib event sample instance maximum 10
   ```

3. Create and configure a trigger:

   # Create a trigger and enter its view. Specify its owner as **owner1** and its name as **triggerA**.

   ```
   [Sysname] snmp mib event trigger owner owner1 name triggerA
   ```

   # Set the sampling interval to 60 seconds. Make sure the interval is greater than or equal to the Event MIB minimum sampling interval.

   ```
   [Sysname-trigger-owner1-triggerA] frequency 60
   ```

   # Specify object OID **1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11** as the monitored object.

   ```
   [Sysname-trigger-owner1-triggerA] oid 1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11
   ```

   # Configure a threshold trigger test. Specify the rising threshold to 80 and the falling threshold to 10 for the test.

   ```
   [Sysname-trigger-owner1-triggerA] test threshold
   [Sysname-trigger-owner1-triggerA-threshold] rising value 80
   [Sysname-trigger-owner1-triggerA-threshold] falling value 10
   [Sysname-trigger-owner1-triggerA-threshold] quit
   ```

   # Enable trigger sampling.

   ```
   [Sysname-trigger-owner1-triggerA] trigger enable
   [Sysname-trigger-owner1-triggerA] quit
   ```

Verifying the configuration

Display Event MIB configuration and statistics.

```
[Sysname] display snmp mib event summary
TriggerFailures               : 0
EventFailures                 : 0
SampleMinimum                 : 50
SampleInstanceMaximum         : 10
SampleInstance                : 1
SampleInstancesHigh           : 1
SampleInstanceLacks           : 0

Configuring NETCONF

About NETCONF

Network Configuration Protocol (NETCONF) is an XML-based network management protocol. It provides programmable mechanisms to manage and configure network devices. Through NETCONF, you can configure device parameters, retrieve parameter values, and collect statistics. For a network that has devices from vendors, you can develop a NETCONF-based NMS system to configure and manage devices in a simple and effective way.

NETCONF structure

NETCONF has the following layers: content layer, operations layer, RPC layer, and transport protocol layer.

Table 1 NETCONF layers and XML layers

NETCONF layer	XML layer	Description
Content	Configuration data, status data, and statistics	Contains a set of managed objects, which can be configuration data, status data, and statistics. For information about the operable data, see the NETCONF XML API reference for the device.
Operations	<get>, <get-config>, <edit-config>…	Defines a set of base operations invoked as RPC methods with XML-encoded parameters. NETCONF base operations include data retrieval operations, configuration operations, lock operations, and session operations. For information about operations supported on the device, see "Supported NETCONF operations."
RPC	<rpc> and <rpc-reply>	Provides a simple, transport-independent framing mechanism for encoding RPCs. The <rpc> and <rpc-reply> elements are used to enclose NETCONF requests and responses (data at the operations layer and the content layer).
Transport protocol	In non-FIPS mode: Console, Telnet, SSH, HTTP, HTTPS, and TLS In FIPS mode: Console, SSH, HTTPS, and TLS	Provides reliable, connection-oriented, serial data links. The following transport layer sessions are available in non-FIPS mode: • CLI sessions, including NETCONF over Telnet sessions, NETCONF over SSH sessions, and NETCONF over console sessions. • NETCONF over SOAP sessions, including NETCONF over SOAP over HTTP sessions and NETCONF over SOAP over HTTPS sessions. The following transport layer sessions are available in FIPS mode: • CLI sessions, including NETCONF over SSH sessions and NETCONF over console sessions. • NETCONF over SOAP over HTTPS sessions.

Basic NETCONF concepts

XML

eXtensible Markup Language (XML) is a simple, text-based data storage language. It describes the content and structure of data exchanged between entities on the Internet.

XML is case sensitive.

NETCONF uses XML-based data encoding for the configuration data and protocol messages. NETCONF messages are XML-based and comply with RFC 4741.

Element

Elements are the basic building blocks in an XML document. They act as containers to store various types of content, including text, child elements, and attributes.

An element encloses content in a pair of start and end tags, in <*element-name*>*content*</*element-name*> format. For example, the **capability** element is `<capability>`*content*`</capability>`.

If an element does not have content, that element is called an empty element. You can present an empty element in a self-closing empty tag in <*element-name*/> format, for example, `<ok/>`.

Attribute

Attributes provide meta-level information about an element. They are added in *name*=*value* format after the element name, within the start tag. For examples, the `xmlns` and `operation` attributes in the following element specify the namespace and operation type, respectively.

```
<Syslog xmlns="http://www.h3c.com/netconf/config:1.0-Syslog"
xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0"   xc:operation="create">
```

Namespace

A namespace is an abstract container or environment created to hold a logical group of unique identifiers or names. An identifier defined in a namespace is associated only with that namespace. Each data module must have a world-unique namespace to avoid element and attribute naming conflicts.

The device supports the following types of namespaces:

- **urn:ietf:params:xml:ns:netconf:base:1.0 namespace**—This namespace defines all NETCONF elements. All NETCONF messages must declare this namespace in the RPC layer.
- **ietf-netconf namespace**—The **urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring** namespace defined in a NETCONF protocol. NETCONF messages for the <get-schema> and <get><netconf-state/></get> operations must declare this namespace.
- **Common namespace**—A namespace that defines elements across service modules. In a packet that uses a common namespace, the namespace is indicated in the <top> element, and the modules are listed under the <top> element.
- **H3C common namespaces**—The http://www.h3c.com/netconf/*ns*:1.0 namespaces. The *ns* argument represents data, config, and action, which represent the data, configuration, and action namespaces, respectively. The common namespaces are shared by all modules. If used, a common namespace is typically specified for the xmlns attribute in the <top> element, and the modules are listed under the <top> element.

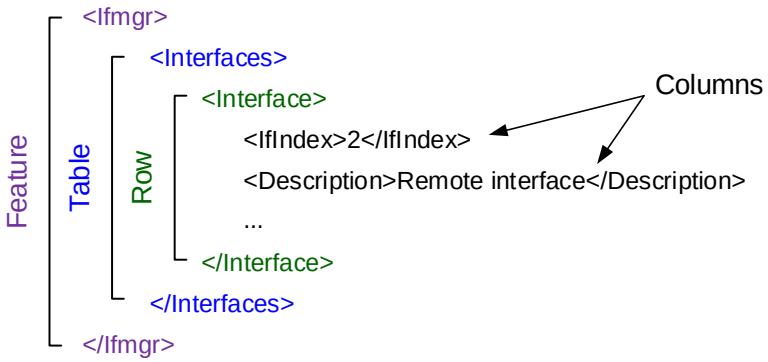
  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
         <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
               <Interfaces>
               </Interfaces>
            </Ifmgr>
         </top>
      </filter>
   </get-bulk>
```

```
</rpc>
```

- **Module-specific namespaces**—A module has its own namespace to define module-specific elements. A packet that uses a module-specific namespace does not have the <top> element. The namespace follows the module name.

  Example:



```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
            <Ifmgr xmlns="http://www.h3c.com/netconf/data:1.0-Ifmgr">
               <Interfaces>
               </Interfaces>
            </Ifmgr>
      </filter>
   </get-bulk>
</rpc>
```

Node, module, table, row, and column

In H3C NETCONF XML AI references, elements are also called nodes. An element might be a module (or feature), table, row, or column node, as shown in Figure 1.

- **Module**—A feature module defines a hierarchy of related nodes. The element name for a module node is the module name.
- **Table**—A table contains rows and columns, with each row representing an object instance and each column containing a parameter for the instance. A table might also contains subtables.
- **Row**—Each row represents an object instance in the table.
- **Column**—Each column contains a parameter for the instance.

Figure 1 Node, module, table, row, and column in NETCONF messages

In Figure 1, the `Ifmgr` element represents the interface management module (Ifmgr). The `Interfaces` element is a table node in the Ifmgr module and it contains a table of interfaces. The `Interface` element is a row node and it contains data about an interface in the interface table. The `IfIndex` and `Description` elements are column nodes that contain the interface index and description of the interface.

NETCONF message format

NETCONF

All NETCONF messages are XML-based and comply with RFC 4741. An incoming NETCONF message must pass XML schema check before it can be processed. If a NETCONF message fails XML schema check, the device sends an error message to the client.

For information about the NETCONF operations supported by the device and the operable data, see the NETCONF XML API reference for the device.

The following example shows a NETCONF message for getting all parameters of all interfaces on the device:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
                 <Interface/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

NETCONF over SOAP

All NETCONF over SOAP messages are XML-based and comply with RFC 4741. NETCONF messages are contained in the <Body> element of SOAP messages. NETCONF over SOAP messages also comply with the following rules:

- SOAP messages must use the SOAP Envelope namespaces.
- SOAP messages must use the SOAP Encoding namespaces.
- SOAP messages cannot contain the following information:
  - DTD reference.
  - XML processing instructions.

The following example shows a NETCONF over SOAP message for getting all parameters of all interfaces on the device:

```
<env:Envelope xmlns:env="http://www.w3.org/2003/05/soap-envelope">
  <env:Header>
    <auth:Authentication env:mustUnderstand="1"
xmlns:auth="http://www.h3c.com/netconf/base:1.0">
      <auth:AuthInfo>800207F0120020C</auth:AuthInfo>
    </auth:Authentication>
  </env:Header>
  <env:Body>
    <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <get-bulk>
        <filter type="subtree">
          <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
              <Interfaces>
                <Interface/>
              </Interfaces>
            </Ifmgr>
          </top>
        </filter>
```

```
      </get-bulk>
    </rpc>
  </env:Body>
</env:Envelope>
```

How to use NETCONF

You can use NETCONF to manage and configure the device by using the methods in Table 2.

Table 2 NETCONF methods for configuring the device

Configuration tool	Login method	Remarks
CLI	• Console port • SSH • Telnet	To perform NETCONF operations, copy valid NETCONF messages to the CLI in XML view.
Custom user interface	N/A	This method requires a NETCONF over SOAP session or NETCONF over SSH session with the device. To use a NETCONF over SOAP session, you must enable NETCONF over SOAP. Then, NETCONF messages will be encapsulated in SOAP messages for transmission.

Protocols and standards

- RFC 3339, *Date and Time on the Internet: Timestamps*
- RFC 4741, *NETCONF Configuration Protocol*
- RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*
- RFC 4743, *Using NETCONF over the Simple Object Access Protocol (SOAP)*
- RFC 5277, *NETCONF Event Notifications*
- RFC 5381, *Experience of Implementing NETCONF over SOAP*
- RFC 5539, *NETCONF over Transport Layer Security (TLS)*
- RFC 6241, *Network Configuration Protocol*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see *Security Configuration Guide*) and non-FIPS mode.

NETCONF tasks at a glance

To configure NETCONF, perform the following tasks:

1. Establishing a NETCONF session
   a. (Optional.) Setting NETCONF session attributes
   b. Establishing NETCONF over SOAP sessions
   c. Establishing NETCONF over SSH sessions
   d. Establishing NETCONF over Telnet or NETCONF over console sessions
   e. Exchanging capabilities

2. (Optional.) Retrieving device configuration information
   - Retrieving device configuration and state information
   - Retrieving non-default settings
   - Retrieving NETCONF information
   - Retrieving YANG file content
   - Retrieving NETCONF session information
3. (Optional.) Filtering data
   - Table-based filtering
   - Column-based filtering
4. (Optional.) Locking or unlocking the running configuration
   a. Locking the running configuration
   b. Unlocking the running configuration
5. (Optional.) Modifying the configuration
6. (Optional.) Managing configuration files
   - Saving the running configuration
   - Loading the configuration
   - Rolling back the configuration
7. (Optional.) Performing CLI operations through NETCONF
8. (Optional.) Subscribing to events
   - Subscribing to syslog events
   - Subscribing to events monitored by NETCONF
   - Subscribing to events reported by modules
   - Canceling an event subscription
9. (Optional.) Terminating NETCONF sessions
10. (Optional.) Returning to the CLI

Establishing a NETCONF session

Restrictions and guidelines for NETCONF session establishment

After a NETCONF session is established, the device automatically sends its capabilities to the client. You must send the capabilities of the client to the device before you can perform any other NETCONF operations.

Before performing a NETCONF operation, make sure no other users are configuring or managing the device. If multiple users simultaneously configure or manage the device, the result might be different from what you expect.

You can use the **`aaa session-limit`** command to set the maximum number of NETCONF sessions that the device can support. If the upper limit is reached, new NETCONF users cannot access the device. For information about this command, see AAA in *Security Configuration Guide*.

Setting NETCONF session attributes

About this task

NETCONF supports the following types of namespaces:

- **Common namespace**—The common namespace is shared by all modules. In a packet that uses the common namespace, the namespace is indicated in the <top> element, and the modules are listed under the <top> element.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
         <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
               <Interfaces>
               </Interfaces>
            </Ifmgr>
         </top>
      </filter>
   </get-bulk>
</rpc>
```

- **Module-specific namespace**—Each module has its own namespace. A packet that uses a module-specific namespace does not have the <top> element. The namespace follows the module name.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
            <Ifmgr xmlns="http://www.h3c.com/netconf/data:1.0-Ifmgr">
               <Interfaces>
               </Interfaces>
            </Ifmgr>
      </filter>
   </get-bulk>
</rpc>
```

The common namespace is incompatible with module-specific namespaces. To set up a NETCONF session, the device and the client must use the same type of namespaces. By default, the common namespace is used. If the client does not support the common namespace, use this feature to configure the device to use module-specific namespaces.

Procedure

1. Enter system view.

   system-view

2. Set the NETCONF session idle timeout time.

   netconf { **agent** | **soap** } **idle-timeout** *minute*

Keyword	Description
agent	Specifies the following sessions: • NETCONF over SSH sessions. • NETCONF over Telnet sessions. • NETCONF over console sessions. By default, the idle timeout time is 0, and the sessions never time out.
soap	Specifies the following sessions:

Keyword	Description
	• NETCONF over SOAP over HTTP sessions. • NETCONF over SOAP over HTTPS sessions. The default setting is 10 minutes.

3. Enable NETCONF logging.

   netconf log source { **all** | { **agent** | **soap** | **web** } * } { **protocol-operation** { **all** | { **action** | **config** | **get** | **set** | **session** | **syntax** | **others** } * } | **row-operation** | **verbose** }

   By default, the device logs only row operations for <action> and <edit-config> operations. NETCONF logging is disabled for all the other types of operations.

   The **web** keyword is not supported in the current software version.

4. Configure NETCONF to use module-specific namespaces.

   netconf capability specific-namespace

   By default, the common namespace is used.

   For the setting to take effect, you must reestablish the NETCONF session.

Establishing NETCONF over SOAP sessions

About this task

You can use a custom user interface to establish a NETCONF over SOAP session to the device and perform NETCONF operations. NETCONF over SOAP encapsulates NETCONF messages into SOAP messages and transmits the SOAP messages over HTTP or HTTPS.

Restrictions and guidelines

You can add an authentication domain to the <UserName> parameter of a SOAP request. The authentication domain takes effect only on the current request.

The mandatory authentication domain configured by using the **netconf soap domain** command takes precedence over the authentication domain specified in the <UserName> parameter of a SOAP request.

Procedure

1. Enter system view.

   system-view

2. Enable NETCONF over SOAP.

   In non-FIPS mode:

   netconf soap { **http** | **https** } **enable**

   In FIPS mode:

   netconf soap https enable

   By default, the NETCONF over SOAP feature is disabled.

3. Set the DSCP value for NETCONF over SOAP packets.

   In non-FIPS mode:

   netconf soap { **http** | **https** } **dscp** *dscp-value*

   In FIPS mode:

   netconf soap https dscp *dscp-value*

   By default, the DSCP value is 0 for NETCONF over SOAP packets.

4. Use an IPv4 ACL to control NETCONF over SOAP access.

In non-FIPS mode:

netconf soap { **http** | **https** } **acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }

In FIPS mode:

netconf soap https acl { *ipv4-acl-number* | **name** *ipv4-acl-name* }

By default, no IPv4 ACL is applied to control NETCONF over SOAP access.

Only clients permitted by the IPv4 ACL can establish NETCONF over SOAP sessions.

5. Specify a mandatory authentication domain for NETCONF users.

   netconf soap domain *domain-name*

   By default, no mandatory authentication domain is specified for NETCONF users. For information about authentication domains, see *Security Configuration Guide*.

6. Use the custom user interface to establish a NETCONF over SOAP session with the device.

   For information about the custom user interface, see the user guide for the interface.

Establishing NETCONF over SSH sessions

Prerequisites

Before establishing a NETCONF over SSH session, make sure the custom user interface can access the device through SSH.

Procedure

1. Enter system view.

   system-view

2. Enable NETCONF over SSH.

   netconf ssh server enable

   By default, NETCONF over SSH is disabled.

3. Specify the listening port for NETCONF over SSH packets.

   netconf ssh server port *port-number*

   By default, the listening port number is 830.

4. Use the custom user interface to establish a NETCONF over SSH session with the device. For information about the custom user interface, see the user guide for the interface.

Establishing NETCONF over Telnet or NETCONF over console sessions

Restrictions and guidelines

To ensure the format correctness of a NETCONF message, do not enter the message manually. Copy and paste the message.

While the device is performing a NETCONF operation, do not perform any other operations, such as pasting a NETCONF message or pressing **Enter**.

For the device to identify NETCONF messages, you must add end mark **]]>]]>** at the end of each NETCONF message. Examples in this document do not necessarily have this end mark. Do add the end mark in actual operations.

Prerequisites

To establish a NETCONF over Telnet session or a NETCONF over console session, first log in to the device through Telnet or the console port.

Procedure

To enter XML view, execute the following command in user view:

xml

If the XML view prompt appears, the NETCONF over Telnet session or NETCONF over console session is established successfully.

Exchanging capabilities

About this task

After a NETCONF session is established, the device sends its capabilities to the client. You must use a hello message to send the capabilities of the client to the device before you can perform any other NETCONF operations.

Hello message from the device to the client

```
<?xml version="1.0" encoding="UTF-8"?><hello
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"><capabilities>...</capabilities><sess
ion-id>1</session-id></hello>]]>]]>
```

The <capabilities> element carries the capabilities supported by the device. The supported capabilities vary by device model.

The <session-id> element carries the unique ID assigned to the NETCONF session.

Hello message from the client to the device

After receiving the hello message from the device, copy the following hello message to notify the device of the capabilities supported by the client:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
     capability-set
   </capability>
 </capabilities>
</hello>
```

Item	Description
capability-set	Specifies a set of capabilities supported by the client. Use the <capability> and </capability> tags to enclose each user-defined capability set.

Retrieving device configuration information

Restrictions and guidelines for device configuration retrieval

During a <get>, <get-bulk>, <get-config>, or <get-bulk-config> operation, NETCONF replaces unidentifiable characters in the retrieved data with question marks (?) before sending the data to the client. If the process for a relevant module is not started yet, the operation returns the following message:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data/>
```

```
</rpc-reply>
```

The <get><netconf-state/></get> operation does not support data filtering.

For more information about the NETCONF operations, see the NETCONF XML API references for the device.

Retrieving device configuration and state information

You can use the following NETCONF operations to retrieve device configuration and state information:

- **<get> operation**—Retrieves all device configuration and state information that matches the specified conditions.
- **<get-bulk> operation**—Retrieves data entries starting from the data entry next to the one with the specified index. One data entry contains a device configuration entry and a state information entry. The returned output does not include the index information.

The <get> message and <get-bulk> message share the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <getoperation>
    <filter>
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
          Specify the module, submodule, table name, and column name
      </top>
    </filter>
  </getoperation>
</rpc>
```

Item	Description
getoperation	Operation name, **get** or **get-bulk**.
filter	Specifies the filtering conditions, such as the module name, submodule name, table name, and column name. • If you specify a module name, the operation retrieves the data for the specified module. If you do not specify a module name, the operation retrieves the data for all modules. • If you specify a submodule name, the operation retrieves the data for the specified submodule. If you do not specify a submodule name, the operation retrieves the data for all submodules. • If you specify a table name, the operation retrieves the data for the specified table. If you do not specify a table name, the operation retrieves the data for all tables. • If you specify only the index column, the operation retrieves the data for all columns. If you specify the index column and any other columns, the operation retrieves the data for the index column and the specified columns.

A <get-bulk> message can carry the **count** and **index** attributes.

Item	Description
index	Specifies the index. If you do not specify this item, the index value starts with 1 by default.
count	Specifies the data entry quantity.

Item	Description

	The **count** attribute complies with the following rules:
	• The **count** attribute can be placed in the module node and table node. In other nodes, it cannot be resolved.
	• When the **count** attribute is placed in the module node, a descendant node inherits this count attribute if the descendant node does not contain the count attribute.
	• The <get-bulk> operation retrieves all the rest data entries starting from the data entry next to the one with the specified index if either of the following conditions occurs:
	  ○ You do not specify the **count** attribute.
	  ○ The number of matching data entries is less than the value of the **count** attribute.

The following <get-bulk> message example specifies the **count** and **index** attributes:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0"
xmlns:base="http://www.h3c.com/netconf/base:1.0">
        <Syslog>
          <Logs xc:count="5">
            <Log>
              <Index>10</Index>
           </Log>
             </Logs>
        </Syslog>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

When retrieving interface information, the device cannot identify whether an integer value for the <IfIndex> element represents an interface name or index. When retrieving VPN instance information, the device cannot identify whether an integer value for the <vrfindex> element represents a VPN name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

The **valuetype** attribute has the following values:

Value	Description
name	The element is carrying a name.
index	The element is carrying an index.
auto	Default value. The device uses the value of the element as a name for information matching. If no match is found, the device uses the value as an index for interface or information matching.

The following example specifies an index-type value for the <IfIndex> element:

```
<rpc xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <getoperation>
    <filter>
```

```
      <top xmlns="http://www.h3c.com/netconf/config:1.0"
xmlns:base="http://www.h3c.com/netconf/base:1.0">
       <VLAN>
        <TrunkInterfaces>
          <Interface>
            <IfIndex base:valuetype="index">1</IfIndex>
          </Interface>
        </TrunkInterfaces>
       </VLAN>
      </top>
    </filter >
  </getoperation>
</rpc>
```

If the <get> or < get-bulk> operation succeeds, the device returns the retrieved data in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Device state and configuration data
  </data>
</rpc-reply>
```

Retrieving non-default settings

The <get-config> and <get-bulk-config> operations are used to retrieve all non-default settings. The <get-config> and <get-bulk-config> messages can contain the <filter> element for filtering data.

The <get-config> and <get-bulk-config> messages are similar. The following is a <get-config> message example:

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
          Specify the module name, submodule name, table name, and column name
      </top>
    </filter>
  </get-config>
</rpc>
```

If the <get-config> or <get-bulk-config> operation succeeds, the device returns the retrieved data in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    Data matching the specified filter
  </data>
</rpc-reply>
```

Retrieving NETCONF information

Use the <get><netconf-state/></get> message to retrieve NETCONF information.

Copy the following text to the client to retrieve NETCONF information:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="m-641" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type='subtree'>
      <netconf-state xmlns='urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring'>
         <getType/>
      </netconf-state>
    </filter>
  </get>
</rpc>
```

If you do not specify a value for *getType*, the retrieval operation retrieves all NETCONF information.

The value for *getType* can be one of the following operations:

Operation	Description
capabilities	Retrieves device capabilities.
datastores	Retrieves databases from the device.
schemas	Retrieves the list of the YANG file names from the device.
sessions	Retrieves session information from the device.
statistics	Retrieves NETCONF statistics.

If the <get><netconf-state/></get> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Retrieved NETCONF information
  </data>
</rpc-reply>
```

Retrieving YANG file content

YANG files save the NETCONF operations supported by the device. You can identify the supported operations by retrieving and analyzing the content of YANG files.

YANG files are integrated in the device software and are named in the format of *yang_identifier@yang_version.yang*. You cannot view the YANG file names by executing the **dir** command. For information about retrieving the YANG file names, see "Retrieving NETCONF information."

Copy the following text to the client to retrieve the YANG file named **H3C-syslog-data@2019-01-01.yang**:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-schema xmlns='urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring'>
    <identifier>H3C-syslog-data</identifier>
```

```
    <version>2019-01-01</version>
    <format>yang</format>
  </get-schema>
</rpc>
```

If the <get-schema> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Content of the specified YANG file
  </data>
</rpc-reply>
```

Retrieving NETCONF session information

Use the <get-sessions> operation to retrieve NETCONF session information of the device.

Copy the following message to the client to retrieve NETCONF session information from the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions/>
</rpc>
```

If the <get-sessions> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions>
    <Session>
      <SessionID>Configuration session ID</SessionID>
      <Line>Line information</Line>
      <UserName>Name of the user creating the session</UserName>
      <Since>Time when the session was created</Since>
      <LockHeld>Whether the session holds a lock</LockHeld>
    </Session>
  </get-sessions>
</rpc-reply>
```

Example: Retrieving a data entry for the interface table

Network configuration

Retrieve a data entry for the interface table.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
```

```
</hello>
```

Retrieve a data entry for the interface table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0"
xmlns:web="http://www.h3c.com/netconf/base:1.0">
        <Ifmgr>
          <Interfaces web:count="1">
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-bulk> operation is successful:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
  <data>
    <top xmlns="http://www.h3c.com/netconf/data:1.0">
      <Ifmgr>
        <Interfaces>
          <Interface>
            <IfIndex>3</IfIndex>
            <Name>GigabitEthernet1/0/2</Name>
            <AbbreviatedName>GE1/0/2</AbbreviatedName>
            <PortIndex>3</PortIndex>
            <ifTypeExt>22</ifTypeExt>
            <ifType>6</ifType>
            <Description>GigabitEthernet1/0/2 Interface</Description>
            <AdminStatus>2</AdminStatus>
            <OperStatus>2</OperStatus>
            <ConfigSpeed>0</ConfigSpeed>
            <ActualSpeed>100000</ActualSpeed>
            <ConfigDuplex>3</ConfigDuplex>
            <ActualDuplex>1</ActualDuplex>
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </data>
</rpc-reply>
```

Example: Retrieving non-default configuration data

Network configuration

Retrieve all non-default configuration data.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve all non-default configuration data.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
  </get-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-config> operation is successful:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/config:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>1307</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1308</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1309</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1311</IfIndex>
                            <VlanType>2</VlanType>
```

```
                    </Interface>
                    <Interface>
                        <IfIndex>1313</IfIndex>
                            <VlanType>2</VlanType>
                    </Interface>
                </Interfaces>
            </Ifmgr>
            <Syslog>
                <LogBuffer>
                    <BufferSize>120</BufferSize>
                </LogBuffer>
            </Syslog>
            <System>
                <Device>
                    <SysName>Sysname</SysName>
                    <TimeZone>
                        <Zone>+11:44</Zone>
                        <ZoneName>beijing</ZoneName>
                    </TimeZone>
                </Device>
            </System>
        </top>
    </data>
</rpc-reply>
```

Example: Retrieving syslog configuration data

Network configuration

Retrieve configuration data for the Syslog module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve configuration data for the Syslog module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
```

```
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Syslog/>
      </top>
    </filter>
  </get-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-config> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/config:1.0">
            <Syslog>
                <LogBuffer>
                    <BufferSize>120</BufferSize>
                </LogBuffer>
            </Syslog>
        </top>
    </data>
</rpc-reply>
```

Example: Retrieving NETCONF session information

Network configuration

Get NETCONF session information.

Procedure

Enter XML view.

```
<Sysname> xml
```

Copy the following message to the client to exchange capabilities with the device:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Copy the following message to the client to get the current NETCONF session information on the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions/>
</rpc>
```

Verifying the configuration

If the client receives a message as follows, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
```

```
    <get-sessions>
        <Session>
            <SessionID>1</SessionID>
            <Line>vty0</Line>
            <UserName></UserName>
            <Since>2019-01-07T00:24:57</Since>
            <LockHeld>false</LockHeld>
        </Session>
    </get-sessions>
</rpc-reply>
```

The output shows the following information:

- The session ID of an existing NETCONF session is 1.
- The login user type is vty0.
- The login time is 2019-01-07T00:24:57.
- The user does not hold the lock of the configuration.

Filtering data

About data filtering

You can define a filter to filter information when you perform a <get>, <get-bulk>, <get-config>, or <get-bulk-config> operation. Data filtering includes the following types:

- **Table-based filtering**—Filters table information.
- **Column-based filtering**—Filters information for a single column.

Restrictions and guidelines for data filtering

For table-based filtering to take effect, you must configure table-based filtering before column-based filtering.

Table-based filtering

About this task

The namespace is **http://www.h3c.com/netconf/base:1.0**. The attribute name is **filter**. For information about the support for table-based match, see the NETCONF XML API references.

Copy the following text to the client to retrieve the longest data with IP address **1.1.1.0** and mask length **24** from the IPv4 routing table:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Route>
         <Ipv4Routes>
           <RouteEntry h3c:filter="IP 1.1.1.0 MaskLen 24 longer"/>
         </Ipv4Routes>
        </Route>
```

```
      </top>
    </filter>
  </get>
</rpc>
```

Restrictions and guidelines

To use table-based filtering, specify a match criterion for the **filter** row attribute.

Column-based filtering

About this task

Column-based filtering includes full match filtering, regular expression match filtering, and conditional match filtering. Full match filtering has the highest priority and conditional match filtering has the lowest priority. When more than one filtering criterion is specified, the one with the highest priority takes effect.

Full match filtering

You can specify an element value in an XML message to implement full match filtering. If multiple element values are provided, the system returns the data that matches all the specified values.

Copy the following text to the client to retrieve configuration data of all interfaces in UP state:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <AdminStatus>1</AdminStatus>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

You can also specify an attribute name that is the same as a column name of the current table at the row to implement full match filtering. The system returns only configuration data that matches this attribute name. The XML message equivalent to the above element-value-based full match filtering is as follows:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top
xmlns="http://www.h3c.com/netconf/data:1.0"xmlns:data="http://www.h3c.com/netconf/dat
a:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface data:AdminStatus="1"/>
          </Interfaces>
        </Ifmgr>
```

```
      </top>
    </filter>
  </get>
</rpc>
```

The above examples show that both element-value-based full match filtering and attribute-name-based full match filtering can retrieve the same index and column information for all interfaces in up state.

Regular expression match filtering

To implement a complex data filtering with characters, you can add a **regExp** attribute for a specific element.

The supported data types include integer, date and time, character string, IPv4 address, IPv4 mask, IPv6 address, MAC address, OID, and time zone.

Copy the following text to the client to retrieve the descriptions of interfaces, of which all the characters must be upper-case letters from A to Z:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <Description h3c:regExp="^[A-Z]*$"/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-config>
</rpc>
```

Conditional match filtering

To implement a complex data filtering with digits and character strings, you can add a **match** attribute for a specific element. Table 3 lists the conditional match operators.

Table 3 Conditional match operators

Operation	Operator	Remarks
More than	match="more:*value*"	More than the specified value. The supported data types include date, digit, and character string.
Less than	match="less:*value*"	Less than the specified value. The supported data types include date, digit, and character string.
Not less than	match="notLess:*value*"	Not less than the specified value. The supported data types include date, digit, and character string.
Not more than	match="notMore:*value*"	Not more than the specified value. The supported data types include date, digit, and character string.

Operation	Operator	Remarks
Equal	match="equal:*value*"	Equal to the specified value. The supported data types include date, digit, character string, OID, and BOOL.
Not equal	match="notEqual:*value*"	Not equal to the specified value. The supported data types include date, digit, character string, OID, and BOOL.
Include	match="include:*string*"	Includes the specified string. The supported data types include only character string.
Not include	match="exclude:*string*"	Excludes the specified string. The supported data types include only character string.
Start with	match="startWith:*string*"	Starts with the specified string. The supported data types include character string and OID.
End with	match="endWith:*string*"	Ends with the specified string. The supported data types include only character string.

Copy the following text to the client to retrieve extension information about the entity whose CPU usage is more than 50%:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Device>
          <ExtPhysicalEntities>
            <Entity>
              <CpuUsage h3c:match="more:50"></CpuUsage>
            </Entity>
          </ExtPhysicalEntities>
        </Device>
      </top>
    </filter>
  </get>
</rpc>
```

Example: Filtering data with regular expression match

Network configuration

Retrieve all data including **Gig** in the **Description** column of the Interfaces table under the Ifmgr module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
           urn:ietf:params:netconf:base:1.0
    </capability>
```

```
  </capabilities>
</hello>
```

Retrieve all data including **Gig** in the **Description** column of the Interfaces table under the Ifmgr module.

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <Description h3c:regExp="(Gig)+"/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>2681</IfIndex>
                        <Description>GigabitEthernet1/0/1 Interface</Description>
                    </Interface>
                    <Interface>
                        <IfIndex>2685</IfIndex>
                        <Description>GigabitEthernet1/0/2 Interface</Description>
                    </Interface>
                    <Interface>
                        <IfIndex>2689</IfIndex>
                        <Description>GigabitEthernet1/0/3 Interface</Description>
                    </Interface>
                 <Interface>
            </Ifmgr>
        </top>
    </data>
</rpc-reply>
```

Example: Filtering data by conditional match

Network configuration

Retrieve data in the **Name** column with the ifindex value not less than 5000 in the Interfaces table under the Ifmgr module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
           urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve data in the **Name** column with the ifindex value not less than 5000 in the Interfaces table under the Ifmgr module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <IfIndex h3c:match="notLess:5000"/>
              <Name/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>7241</IfIndex>
                        <Name>NULL0</Name>
```

```
                    </Interface>
                </Interfaces>
            </Ifmgr>
        </top>
    </data>
</rpc-reply>
```

Locking or unlocking the running configuration

About configuration locking and unlocking

Multiple methods are available for configuring the device, such as CLI, NETCONF, and SNMP. Before configuring, managing, or troubleshooting the device, you can lock the configuration to prevent other users from changing the device configuration. After you lock the configuration, only you can perform <edit-config> operations to change the configuration or unlock the configuration. Other users can only read the configuration.

If you close your NETCONF session, the system unlocks the configuration. You can also manually unlock the configuration.

Restrictions and guidelines for configuration locking and unlocking

The <lock> operation locks the running configuration of the device. You cannot use it to lock the configuration for a specific module.

Locking the running configuration

Copy the following text to the client to lock the running configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <lock>
      <target>
        <running/>
      </target>
    </lock>
  </rpc>
```

If the <lock> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
     <ok/>
</rpc-reply>
```

Unlocking the running configuration

Copy the following text to the client to unlock the running configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <unlock>
```

```
      <target>
        <running/>
      </target>
    </unlock>
  </rpc>
```

If the <unlock> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Locking the running configuration

Network configuration

Lock the device configuration so other users cannot change the device configuration.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <capabilities>
        <capability>
            urn:ietf:params:netconf:base:1.0
        </capability>
    </capabilities>
</hello>
```

Lock the configuration.

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <lock>
      <target>
        <running/>
      </target>
    </lock>
  </rpc>
```

Verifying the configuration

If the client receives the following response, the <lock> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

If another client sends a lock request, the device returns the following response:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
  <error-type>protocol</error-type>
```

```
  <error-tag>lock-denied</error-tag>
  <error-severity>error</error-severity>
  <error-message xml:lang="en"> Lock failed because the NETCONF lock is held by another session.</error-message>
  <error-info>
    <session-id>1</session-id>
  </error-info>
  </rpc-error>
</rpc-reply>
```

The output shows that the <lock> operation failed. The client with session ID 1 is holding the lock,

Modifying the configuration

About the <edit-config> operation

The <edit-config> operation includes the following operations: merge, create, replace, remove, delete, default-operation, error-option, test-option, and incremental. For more information about the operations, see "Supported NETCONF operations."

Procedure

Copy the following text to perform the <edit-config> operation:

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target><running></running></target>
    <error-option>
       error-option
    </error-option>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        Specify the module name, submodule name, table name, and column name
      </top>
    </config>
  </edit-config>
</rpc>
```

The <error-option> element indicates the action to be taken in response to an error that occurs during the operation. It has the following values:

Value	Description
stop-on-error	Stops the <edit-config> operation.
continue-on-error	Continues the <edit-config> operation.
rollback-on-error	Rolls back the configuration to the configuration before the <edit-config> operation was performed. By default, an <edit-config> operation cannot be performed while the device is rolling back the configuration. If the rollback time exceeds the maximum time that the client can wait, the client determines that the <edit-config> operation has failed and performs the operation again. Because the previous rollback is not

Value	Description
	completed, the operation triggers another rollback. If this process repeats itself, CPU and memory resources will be exhausted and the device will reboot. To allow an <edit-config> operation to be performed during a configuration rollback, perform an <action> operation to change the value of the **DisableEditConfigWhenRollback** attribute to **false**.

If the <edit-config> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0">
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

You can also perform the <get> operation to verify that the current element value is the same as the value specified through the <edit-config> operation.

Example: Modifying the configuration

Network configuration

Change the log buffer size for the Syslog module to 512.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

Change the log buffer size for the Syslog module to 512.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0" web:operation="merge">
        <Syslog>
          <LogBuffer>
            <BufferSize>512</BufferSize>
          </LogBuffer>
        </Syslog>
      </top>
    </config>
  </edit-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <edit-config> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Saving the running configuration

About the <save> operation

A <save> operation saves the running configuration to a configuration file and specifies the file as the main next-startup configuration file.

Restrictions and guidelines

The <save> operation is resource intensive. Do not perform this operation when system resources are heavily occupied.

Procedure

Copy the following text to the client:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save OverWrite="false" Binary-only="false" Safely="false">
    <file>Configuration file name</file>
  </save>
</rpc>
```

Item	Description
file	Specifies a .cfg configuration file by its name. The name must start with the storage medium name. If you specify the file column, a file name is required. If the **Binary-only** attribute is **false**, the device saves the running configuration to both the text and binary configuration files. • If the specified .cfg file does not exist, the device creates the binary and text configuration files to save the running configuration. • If you do not specify the file column, the device saves the running configuration to the text and binary next-startup configuration files.
OverWrite	Determines whether to overwrite the specified file if the file already exists. The following values are available: • **true**—Overwrite the file. • **false**—Do not overwrite the file. The running configuration cannot be saved, and the system displays an error message. The default value is **true**.
Binary-only	Determines whether to save the running configuration only to the binary configuration file. The following values are available: • **true**—Save the running configuration only to the binary configuration file. ○ If **file** specifies a nonexistent file, the <save> operation fails.

Item	Description
	○ If you do not specify the file column, the device identifies whether the main next-startup configuration file is specified. If yes, the device saves the running configuration to the corresponding binary file. If not, the <save> operation fails. • **false**—Save the running configuration to both the text and binary configuration files. For more information, see the description for the file column in this table. Saving the running configuration to both the text and binary configuration files requires more time. The default value is **false**.
Safely	Determines whether to save the configuration file in safe mode or fast mode. Available values: • **true**—Saves the configuration in safe mode. In this mode, the system saves the configuration in a temporary file and starts overwriting the target next-startup configuration file after the save operation is complete. If a disruptive event such as a reboot or power failure occurs during the save operation, the device can still start up with the original next-startup configuration file. • **false**—Saves the configuration in fast mode. In this mode, the system directly overwrites the target next-startup configuration file. If a disruptive event such as a reboot, power failure, out-of-memory, out-of-storage event occurs during this process, the next-startup configuration file is lost. You must specify a new startup configuration file after the device reboots. By default, the Safely attribute is set to **false** if you do not specify a value for it. Safe mode is slower than fast mode, but more secure. As a best practice, use the safe mode if the power source is not reliable or you are remotely configuring the device.

If the <save> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Saving the running configuration

Network configuration

Save the running configuration to the **config.cfg** file.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Save the running configuration of the device to the **config.cfg** file.

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save>
    <file>config.cfg</file>
  </save>
</rpc>
```

Verifying the configuration

If the client receives the following response, the <save> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Loading the configuration

About the <load> operation

The <load> operation merges the configuration from a configuration file into the running configuration as follows:

- Loads settings that do not exist in the running configuration.
- Overwrites settings that already exist in the running configuration.

Restrictions and guidelines

When you perform a <load> operation, follow these restrictions and guidelines:

- The <load> operation is resource intensive. Do not perform this operation when the system resources are heavily occupied.
- Some settings in a configuration file might conflict with the existing settings. For the settings in the file to take effect, delete the existing conflicting settings, and then load the configuration file.

Procedure

Copy the following text to the client to load a configuration file for the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <load>
    <file>Configuration file name</file>
  </load>
</rpc>
```

The configuration file name must start with the storage media name and end with the **.cfg** extension.

If the <load> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Rolling back the configuration

Restrictions and guidelines

The <rollback> operation is resource intensive. Do not perform this operation when the system resources are heavily occupied.

By default, an <edit-config> operation cannot be performed while the device is rolling back the configuration. To allow an <edit-config> operation to be performed during a configuration rollback, perform an <action> operation to change the value of the **DisableEditConfigWhenRollback** attribute to **false**.

Rolling back the configuration based on a configuration file

Copy the following text to the client to roll back the running configuration to the configuration in a configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rollback>
    <file>Specify the configuration file name</file>
  </rollback>
</rpc>
```

If the <rollback> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Rolling back the configuration based on a rollback point

About this task

You can roll back the running configuration based on a rollback point when one of the following situations occurs:

- A NETCONF client sends a rollback request.
- The NETCONF session idle time is longer than the rollback idle timeout time.
- A NETCONF client is unexpectedly disconnected from the device.

Restrictions and guidelines

Multiple users might simultaneously configure the device. As a best practice, lock the system before rolling back the configuration to prevent other users from modifying the running configuration.

Procedure

1. Lock the running configuration. For more information, see "Locking or unlocking the running configuration."
2. Enable configuration rollback based on a rollback point.

   # Copy the following text to the client to perform a <save-point>/<begin> operation:

   ```
   <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
         <save-point>
           <begin>
             <confirm-timeout>100</confirm-timeout>
   ```

```
      </begin>
     </save-point>
</rpc>
```

Item	Description
confirm-timeout	Specifies the rollback idle timeout time in the range of 1 to 65535 seconds. The default is 600 seconds. This item is optional.

If the <save-point/begin> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <save-point>
       <commit>
          <commit-id>1</commit-id>
       </commit>
    </save-point>
  </data>
</rpc-reply>
```

3. Modify the running configuration. For more information, see "Modifying the configuration."
4. Mark the rollback point.

   The system supports a maximum of 50 rollback points. If the limit is reached, specify the **force** attribute for the <save-point>/<commit> operation to overwrite the earliest rollback point.

   # Copy the following text to the client to perform a <save-point>/<commit> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <commit>
      <label>SUPPORT VLAN<label>
      <comment>vlan 1 to 100 and interfaces.</comment>
     </commit>
  </save-point>
</rpc>
```

   The <label> and <comment> elements are optional.

   If the <save-point>/<commit> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <save-point>
       <commit>
          <commit-id>2</commit-id>
       </commit>
    </save-point>
  </data>
</rpc-reply>
```

5. Retrieve the rollback point configuration records.

   The following text shows the message format for a <save-point/get-commits> request:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commits>
      <commit-id/>
```

```
      <commit-index/>
      <commit-label/>
    </get-commits>
  </save-point>
</rpc>
```

Specify the <commit-id/>, <commit-index/>, or <commit-label/> element to retrieve the specified rollback point configuration records. If no element is specified, the operation retrieves records for all rollback point settings.

Copy the following text to the client to perform a <save-point>/<get-commits> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commits>
      <commit-label>SUPPORT VLAN</commit-label>
    </get-commits>
  </save-point>
</rpc>
```

If the <save-point/get-commits> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data>
      <save-point>
         <commit-information>
           <CommitID>2</CommitID>
           <TimeStamp>Sun Jan 1 11:30:28 2019</TimeStamp>
           <UserName>test</UserName>
           <Label>SUPPORT VLAN</Label>
         </commit-information>
    </save-point>
  </data>
</rpc-reply>
```

6. Retrieve the configuration data corresponding to a rollback point.

The following text shows the message format for a <save-point>/<get-commit-information> request:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commit-information>
       <commit-information>
         <commit-id/>
         <commit-index/>
         <commit-label/>
       </commit-information>
       <compare-information>
         <commit-id/>
         <commit-index/>
         <commit-label/>
       </compare-information>
    </get-commit-information>
  </save-point>
</rpc>
```

Specify one of the following elements: <commit-id/>, <commit-index/>, and <commit-label/>. The <compare-information> element is optional.

Item	Description
commit-id	Uniquely identifies a rollback point.
commit-index	Specifies 50 most recently configured rollback points. The value of 0 indicates the most recently configured one and 49 indicates the earliest configured one.
commit-label	Specifies a unique label for a rollback point.
get-commit-information	Retrieves the configuration data corresponding to the most recently configured rollback point.

Copy the following text to the client to perform a <save-point>/<get-commit-information> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commit-information>
               <commit-information>
                  <commit-label>SUPPORT VLAN</commit-label>
               </commit-information>
    </get-commit-information>
  </save-point>
</rpc>
```

If the <save-point/get-commit-information> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data>
     <save-point>
        <commit-information>
           <content>
              …
              interface vlan 1
              …
           </content>
        </commit-information>
     </save-point>
   </data>
</rpc-reply>
```

7. Roll back the configuration based on a rollback point.

The configuration can also be automatically rolled back based on the most recently configured rollback point when the NETCONF session idle timer expires.

Copy the following text to the client to perform a <save-point>/<rollback> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <rollback>
      <commit-id/>
      <commit-index/>
      <commit-label/>
    </rollback>
```

```
  </save-point>
</rpc>
```

Specify one of the following elements: <commit-id/>, <commit-index/>, and <commit-label/>. If no element is specified, the operation rolls back configuration based on the most recently configured rollback point.

Item	Description
commit-id	Uniquely identifies a rollback point.
commit-index	Specifies 50 most recently configured rollback points. The value of 0 indicates the most recently configured one and 49 indicates the earliest configured one.
commit-label	Specifies the unique label of a rollback point.

If the <save-point/rollback> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok></ok>
</rpc-reply>
```

8. End the rollback configuration.

   # Copy the following text to the client to perform a <save-point>/<end> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <end/>
  </save-point>
</rpc>
```

   If the <save-point/end> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

9. Unlock the configuration. For more information, see "Locking or unlocking the running configuration."

Performing CLI operations through NETCONF

About CLI operations through NETCONF

You can enclose command lines in XML messages to configure the device.

Restrictions and guidelines

Performing CLI operations through NETCONF is resource intensive. As a best practice, do not perform the following tasks:

- Enclose multiple command lines in one XML message.
- Use NETCONF to perform a CLI operation when other users are performing NETCONF CLI operations.

Procedure

Copy the following text to the client to execute the commands:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
      Commands
    </Execution>
  </CLI>
</rpc>
```

The <Execution> element can contain multiple commands, with one command on one line.

If the CLI operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
      <![CDATA[Responses to the commands]]>
    </Execution>
  </CLI>
</rpc-reply>
```

Example: Performing CLI operations

Network configuration

Send the **`display vlan`** command to the device.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Copy the following text to the client to execute the **`display vlan`** command:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
          display vlan
    </Execution>
  </CLI>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution><![CDATA[
<Sysname>display vlan
 Total VLANs: 1
 The VLANs include:
 1(default)
   ]]>
   </Execution>
  </CLI>
</rpc-reply>
```

Subscribing to events

About event subscription

When an event takes place on the device, the device sends information about the event to NETCONF clients that have subscribed to the event.

Restrictions and guidelines

Event subscription is not supported for NETCONF over SOAP sessions.

A subscription takes effect only on the current session. It is canceled when the session is terminated.

If you do not specify the event stream to be subscribed to, the device sends syslog event notifications to the NETCONF client.

Subscribing to syslog events

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>NETCONF</stream>
      <filter>
        <event xmlns="http://www.h3c.com/netconf/event:1.0">
          <Code>code</Code>
            <Group>group</Group>
              <Severity>severity</Severity>
        </event>
      </filter>
      <startTime>start-time</startTime>
      <stopTime>stop-time</stopTime>
   </create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. The name for the syslog event stream is **NETCONF**.
event	Specifies the event. For information about the events to which you can subscribe, see the system log message references for the device.
code	Specifies the mnemonic symbol of the log message.
group	Specifies the module name of the log message.
severity	Specifies the severity level of the log message.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

If the subscription fails, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
   <error-severity>error-severity</error-severity>
   <error-message xml:lang="en">error-message</error-message>
</rpc-error>
</rpc-reply>
```

For more information about error messages, see RFC 4741.

Subscribing to events monitored by NETCONF

After you subscribe to events as described in this section, NETCONF regularly polls the subscribed events and sends the events that match the subscription condition to the NETCONF client.

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<create-subscription xmlns='urn:ietf:params:xml:ns:netconf:notification:1.0'>
  <stream>NETCONF_MONITOR_EXTENSION</stream>
  <filter>
    <NetconfMonitor xmlns='http://www.h3c.com/netconf/monitor:1.0'>
      <XPath>XPath</XPath>
      <Interval>interval</Interval>
      <ColumnConditions>
        <ColumnCondition>
          <ColumnName>ColumnName</ColumnName>
          <ColumnValue>ColumnValue</ColumnValue>
```

```
          <ColumnCondition>ColumnCondition</ColumnCondition>
        </ColumnCondition>
      </ColumnConditions>
      <MustIncludeResultColumns>
        <ColumnName>columnName</ColumnName>
      </MustIncludeResultColumns>
    </NetconfMonitor>
  </filter>
<startTime>start-time</startTime>
<stopTime>stop-time</stopTime>
</create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. The name for the event stream is **NETCONF_MONITOR_EXTENSION**.
NetconfMonitor	Specifies the filtering information for the event.
XPath	Specifies the path of the event in the format of *ModuleName*[/*SubmoduleName*]/*TableName*.
interval	Specifies the interval for NETCONF to obtain events that matches the subscription condition. The value range is 1 to 4294967 seconds. The default value is 300 seconds.
ColumnName	Specifies the name of a column in the format of [*GroupName*.]*ColumnName*.
ColumnValue	Specifies the baseline value.
ColumnCondition	Specifies the operator: • **more**. • **less**. • **notLess**. • **notMore**. • **equal**. • **notEqual**. • **include**. • **exclude**. • **startWith**. • **endWith**. Choose an operator according to the type of the baseline value.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Subscribing to events reported by modules

After you subscribe to events as described in this section, the specified modules report subscribed events to NETCONF. NETCONF sends the events to the NETCONF client.

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xs="http://www.h3c.com/netconf/base:1.0">
<create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
<stream>XXX_STREAM</stream>
   <filter type="subtree">
<event xmlns="http://www.h3c.com/netconf/event:1.0/xxx-features-list-name:1.0">
       <ColumnName xs:condition="Condition">value</ColumnName>
</event>
</filter>
<startTime>start-time</startTime>
<stopTime>stop-time</stopTime>
</create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. Supported event streams vary by device model.
event	Specifies the event name. An event stream includes multiple events. The events use the same namespaces as the event stream.
ColumnName	Specifies the name of a column.
Condition	Specifies the operator: • **more**. • **less**. • **notLess**. • **notMore**. • **equal**. • **notEqual**. • **include**. • **exclude**. • **startWith**. • **endWith**. Choose an operator according to the type of the baseline value.
value	Specifies the baseline value for the column.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Canceling an event subscription

Copy the following message to the client to cancel a subscription:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <cancel-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>XXX_STREAM</stream>
  </cancel-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream.

If the cancelation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

If the subscription to be canceled does not exist, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
   <error-severity>error-severity</error-severity>
<error-message xml:lang="en">The subscription stream to be canceled doesn't exist: Stream name=XXX_STREAM.</error-message>
</rpc-error>
</rpc-reply>
```

Example: Subscribing to syslog events

Network configuration

Configure a client to subscribe to syslog events with no time limitation. After the subscription, all events on the device are sent to the client before the session between the device and client is terminated.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Subscribe to syslog events with no time limitation.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>NETCONF</stream>
  </create-subscription>
</rpc>
```

Verifying the configuration

If the client receives the following response, the subscription is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

When another client (192.168.100.130) logs in to the device, the device sends a notification to the client that has subscribed to all events:

```
<?xml version="1.0" encoding="UTF-8"?>
<notification xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <eventTime>2019-01-04T12:30:52</eventTime>
    <event xmlns="http://www.h3c.com/netconf/event:1.0">
        <Group>SHELL</Group>
        <Code>SHELL_LOGIN</Code>
        <Slot>1</Slot>
        <Severity>Notification</Severity>
        <context>VTY logged in from 192.168.100.130.</context>
    </event>
</notification>
```

Terminating NETCONF sessions

About NETCONF session termination

NETCONF allows one client to terminate the NETCONF sessions of other clients. A client whose session is terminated returns to user view.

Procedure

Copy the following message to the client to terminate a NETCONF session:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>
      Specified session-ID
    </session-id>
  </kill-session>
</rpc>
```

If the <kill-session> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
```

```
</rpc-reply>
```

Example: Terminating another NETCONF session

Network configuration

The user whose session's ID is 1 terminates the session with session ID 2.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Terminate the session with session ID 2.

```
<rpc message-id="100"xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>2</session-id>
  </kill-session>
</rpc>
```

Verifying the configuration

If the client receives the following text, the NETCONF session with session ID 2 has been terminated, and the client with session ID 2 has returned from XML view to user view:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Returning to the CLI

Restrictions and guidelines

Before returning from XML view to the CLI, you must first complete capability exchange between the device and the client.

Procedure

Copy the following text to the client to return from XML view to the CLI:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <close-session/>
</rpc>
```

When the device receives the close-session request, it sends the following response and returns to CLI's user view:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
   <ok/>
</rpc-reply>
```

Supported NETCONF operations

This chapter describes NETCONF operations available with Comware 7.

action

Usage guidelines

This operation sends a non-configuration operation instruction to the device, for example, a reset instruction.

XML example

Clear statistics information for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <action>
    <top xmlns="http://www.h3c.com/netconf/action:1.0">
      <Ifmgr>
            <ClearAllIfStatistics>
                <Clear>
                </Clear>
        </ClearAllIfStatistics>
      </Ifmgr>
    </top>
  </action>
</rpc>
```

CLI

Usage guidelines

This operation executes CLI commands.

A request message encloses commands in the <CLI> element. A response message encloses the command output in the <CLI> element.

You can use the following elements to execute commands:

- **Execution**—Executes commands in user view.
- **Configuration**—Executes commands in system view. To execute commands in a lower-level view of the system view, use the <Configuration> element to enter the view first.

  To use this element, include the **exec-use-channel** attribute and specify a value for the attribute:

  - **false**—Executes commands without using a channel.
  - **true**—Executes commands by using a temporary channel. The channel is automatically closed after the execution.
  - **persist**—Executes commands by using the persistent channel for the session.

    To use the persistent channel, first perform an <Open-channel> operation to open the persistent channel. If you do not do so, the system will automatically open the persistent channel.

    After using the persistent channel, perform a <Close-channel> operation to close the channel and return to system view. If you do not perform an <Open-channel> operation, the system stays in the view and will execute subsequent commands in the view.

You can also specify the **error-when-rollback** attribute in the <Configuration> element to indicate whether CLI operations are allowed during a configuration error-triggered configuration rollback. This attribute takes effect only if the value of the <error-option> element in <edit-config> operations is set to **rollback-on-error**. It has the following values:

- **true**—Rejects CLI operation requests and returns error messages.
- **false (the default)**—Allows CLI operations.

For CLI operations to be correctly performed, set the value of the **error-when-rollback** attribute to **true**.

A NETCONF session supports only one persistent channel and but supports multiple temporary channels.

This operation does not support executing interactive CLI commands.

You cannot execute the **quit** command by using a channel to exit user view.

XML example

Execute the **vlan 3** command in system view without using a channel.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
     <Configuration exec-use-channel="false" error-when-rollback="true">vlan
3</Configuration>
  </CLI>
</rpc>
```

close-session

Usage guidelines

This operation terminates the current NETCONF session, unlocks the configuration, and releases the resources (for example, memory) used by the session. After this operation, you exit the XML view.

XML example

Terminate the current NETCONF session.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<close-session/>
</rpc>
```

edit-config: create

Usage guidelines

This operation creates target configuration items.

To use the **create** attribute in an <edit-config> operation, you must specify the target configuration item.

- If the table supports creating a target configuration item and the item does not exist, the operation creates the item and configures the item.
- If the specified item already exists, a data-exist error message is returned.

XML example

Set the buffer size to 120.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Syslog xmlns="http://www.h3c.com/netconf/config:1.0-Syslog"
xc:operation="create">
           <LogBuffer>
             <BufferSize>120</BufferSize>
          </LogBuffer>
        </Syslog>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: delete

Usage guidelines

This operation deletes the specified configuration.

- If the specified target has only the table index, the operation removes all configuration of the specified target, and the target itself.
- If the specified target has the table index and configuration data, the operation removes the specified configuration data of this target.
- If the specified target does not exist, an error message is returned, showing that the target does not exist.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **delete**.

edit-config: merge

Usage guidelines

This operation commits target configuration items to the running configuration.

To use the **merge** attribute in an <edit-config> operation, you must specify the target configuration item (on a specific level):

- If the specified item exists, the operation directly updates the setting for the item.
- If the specified item does not exist, the operation creates the item and configures the item.
- If the specified item does not exist and it cannot be created, an error message is returned.

XML example

The XML data format is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **merge**.

edit-config: remove

Usage guidelines

This operation removes the specified configuration.

- If the specified target has only the table index, the operation removes all configuration of the specified target, and the target itself.
- If the specified target has the table index and configuration data, the operation removes the specified configuration data of this target.
- If the specified target does not exist, or the XML message does not specify any targets, a success message is returned.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **remove**.

edit-config: replace

Usage guidelines

This operation replaces the specified configuration.

- If the specified target exists, the operation replaces the configuration of the target with the configuration carried in the message.
- If the specified target does not exist but is allowed to be created, the operation creates the target and then applies the configuration.
- If the specified target does not exist and is not allowed to be created, the operation is not conducted and an invalid-value error message is returned.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **replace**.

edit-config: test-option

Usage guidelines

This operation determines whether to commit a configuration item in an <edit-configure> operation. The <test-option> element has one of the following values:

- **test-then-set**—Performs a syntax check, and commits an item if the item passes the check. If the item fails the check, the item is not committed. This is the default test-option value.
- **set**—Commits the item without performing a syntax check.
- **test-only**—Performs only a syntax check. If the item passes the check, a success message is returned. Otherwise, an error message is returned.

XML example

Test the configuration for an interface.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <test-option>test-only</test-option>
```

```
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr xc:operation="merge">
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222</Description>
                <ConfigSpeed>2</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
               </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: default-operation

Usage guidelines

This operation modifies the running configuration of the device by using the default operation method.

NETCONF uses one of the following operation attributes to modify configuration: **merge**, **create**, **delete**, and **replace**. If you do not specify an operation attribute for an edit-config message, NETCONF uses the default operation method. The value specified for the <default-operation> element takes effect only once. If you do not specify an operation attribute or the default operation method for an <edit-config> message, **merge** always applies.

The <default-operation> element has the following values:

- **merge**—Default value for the <default-operation> element.
- **replace**—Value used when the operation attribute is not specified and the default operation method is specified as **replace**.
- **none**—Value used when the operation attribute is not specified and the default operation method is specified as **none**. If this value is specified, the <edit-config> operation is used only for schema verification rather than issuing a configuration. If the schema verification is passed, a successful message is returned. Otherwise, an error message is returned.

XML example

Issue an empty operation for schema verification purposes.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <default-operation>none</default-operation>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
```

```
            <IfIndex>262</IfIndex>
            <Description>222222</Description>
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </config>
</edit-config>
</rpc>
```

edit-config: error-option

Usage guidelines

This operation determines the action to take in case of a configuration error.

The <error-option> element has the following values:

- **stop-on-error**—Stops the operation and returns an error message. This is the default error-option value.
- **continue-on-error**—Continues the operation and returns an error message.
- **rollback-on-error**—Rolls back the configuration.

XML example

Issue the configuration for two interfaces, setting the <error-option> element to **continue-on-error**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <error-option>continue-on-error</error-option>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr xc:operation="merge">
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222</Description>
                <ConfigSpeed>1024</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
            </Interface>
            <Interface>
              <IfIndex>263</IfIndex>
              <Description>333</Description>
                <ConfigSpeed>1024</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
```

```
  </edit-config>
</rpc>
```

edit-config: incremental

Usage guidelines

This operation adds configuration data to a column without affecting the original data.

The **incremental** attribute applies to a list column such as the vlan permitlist column.

You can use the **incremental** attribute for <edit-config> operations with an attribute other than **replace**.

Support for the **incremental** attribute varies by module. For more information, see NETCONF XML API references.

XML example

Add VLANs 1 through 10 to an untagged VLAN list that has untagged VLANs 12 through 15.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <VLAN xc:operation="merge">
          <HybridInterfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <UntaggedVlanList  h3c:incremental="true">1-10</UntaggedVlanList>
               </Interface>
          </HybridInterfaces>
        </VLAN>
      </top>
    </config>
  </edit-config>
</rpc>
```

get

Usage guidelines

This operation retrieves device configuration and state information.

XML example

Retrieve device configuration and state information for the Syslog module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Syslog>
```

```
        </Syslog>
      </top>
    </filter>
  </get>
</rpc>
```

get-bulk

Usage guidelines

This operation retrieves a number of data entries (including device configuration and state information) starting from the data entry next to the one with the specified index.

XML example

Retrieve device configuration and state information for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces xc:count="5" xmlns:xc="http://www.h3c.com/netconf/base:1.0">
            <Interface/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

get-bulk-config

Usage guidelines

This operation retrieves a number of non-default configuration data entries starting from the data entry next to the one with the specified index.

XML example

Retrieve non-default configuration for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk-config>
</rpc>
```

get-config

Usage guidelines

This operation retrieves non-default configuration data. If no non-default configuration data exists, the device returns a response with empty data.

XML example

Retrieve non-default configuration data for the interface table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
           <Interfaces>
              <Interface/>
            </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-config>
</rpc>
```

get-sessions

Usage guidelines

This operation retrieves information about all NETCONF sessions in the system. You cannot specify a session ID to retrieve information about a specific NETCONF session.

XML example

Retrieve information about all NETCONF sessions in the system.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<get-sessions/>
</rpc>
```

kill-session

Usage guidelines

This operation terminates the NETCONF session for another user. This operation cannot terminate the NETCONF session for the current user.

XML example

Terminate the NETCONF session with session ID 1.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>1</session-id>
```

```
  </kill-session>
</rpc>
```

load

Usage guidelines

This operation loads the configuration. After the device finishes a <load> operation, the configuration in the specified file is merged into the running configuration of the device.

XML example

Merge the configuration in file **a1.cfg** to the running configuration of the device.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <load>
    <file>a1.cfg</file>
  </load>
</rpc>
```

lock

Usage guidelines

This operation locks the configuration. After you lock the configuration, other users cannot perform <edit-config> operations. Other NETCONF operations are allowed.

After a user locks the configuration, other users cannot use NETCONF or any other configuration methods such as CLI and SNMP to configure the device.

XML example

Lock the configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <lock>
    <target>
        <running/>
    </target>
</lock>
</rpc>
```

rollback

Usage guidelines

This operation rolls back the configuration. To do so, you must specify the configuration file in the <file> element. After the device finishes the <rollback> operation, the current device configuration is totally replaced with the configuration in the specified configuration file.

XML example

Roll back the running configuration to the configuration in file **1A.cfg**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rollback>
    <file>1A.cfg</file>
  </rollback>
</rpc>
```

save

Usage guidelines

This operation saves the running configuration. You can use the <file> element to specify a file for saving the configuration. If the text does not include the file column, the running configuration is automatically saved to the main next-startup configuration file.

The **OverWrite** attribute determines whether the running configuration overwrites the original configuration file when the specified file already exists.

The **Binary-only** attribute determines whether to save the running configuration only to the binary configuration file.

The **Safely** attribute determines whether to save the configuration file in safe mode or fast mode.

XML example

Save the running configuration to file **test.cfg**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save OverWrite="false" Binary-only="true">
    <file>test.cfg</file>
  </save>
</rpc>
```

unlock

Usage guidelines

This operation unlocks the configuration, so other users can configure the device.

Terminating a NETCONF session automatically unlocks the configuration.

XML example

Unlock the configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<unlock>
    <target>
        <running/>
    </target>
</unlock>
</rpc>
```

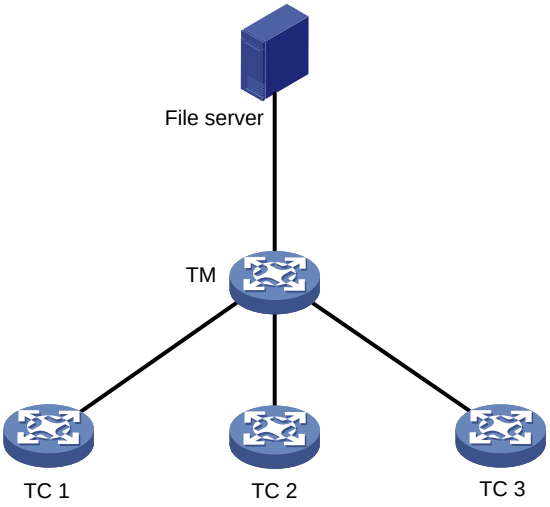
Configuring SmartMC

About SmartMC



Smart Management Center (SmartMC) centrally manages and maintains dispersed network devices at network edges. In a SmartMC network, only one device acts as the commander and the remaining devices all act as members. SmartMC provides the following features for you to manage the members from the commander:

- Configuration file backup and download.
- Software upgrade.
- Configuration deployment.
- Faulty member replacement.

SmartMC network framework

Figure 1 shows the basic framework of a SmartMC network.

Figure 1 SmartMC network framework

The SmartMC network contains the following elements:

- **Commander**—Also called topology master (TM), which manages all members in the SmartMC network.
- **Member**—Also called topology client (TC), which is managed by the commander.
- **File server**—Stores startup software images and configuration files for the commander and members.

SmartMC network establishment

A SmartMC network can be established automatically or manually. In an automatically established SmartMC network, the commander obtains member information through NETCONF sessions to form the network topology. The member information includes port information, LLDP neighbor information, STP information, device type, and software version. In a manually established SmartMC network, the commander obtains member's LLDP neighbor information through NETCONF sessions and member's hardware information through SNMP Get operations.

Automatic SmartMC network establishment

The commander and members use the following procedure to establish a SmartMC network:

1. After SmartMC is enabled, the commander broadcasts a SmartMC packet at an interval of 15 seconds to detect members in the network. The SmartMC packet contains information of the commander, such as its bridge MAC address and the IP address of VLAN-interface 1.
2. When a member receives the packet, it records the commander information, and returns a response packet to the commander. The response packet contains information of the member, such as its bridge MAC address and the IP address of VLAN-interface 1.
3. When the commander receives the response packet, it initiates a NETCONF session to the member with the default username **admin** and the default password **admin**. The commander then obtains detailed information about the member through the session, including port information, LLDP neighbor information, STP information, device type, and software version.
4. The commander establishes a connection to the member for tracking the liveliness of the member, and adds the member to the SmartMC network.
5. Based on the LLDP neighbor information obtained from all members, the commander forms a SmartMC topology.

After the SmartMC network is established, the commander and members check for the existence of each other by exchanging SmartMC packets.

- When a member receives a SmartMC broadcast packet from the commander, it compares the bridge MAC address in the packet with the recorded bridge MAC address. If the two bridge MAC addresses are the same, the member returns a response packet to the commander. If the member does not receive a broadcast packet from the commander within the time limit, the member determines that the commander does not exist in the network anymore. Then, the member clears the commander information. The time limit is a random value in the range of 60 to 120 seconds.
- When the commander receives a response packet from a member, it compares the bridge MAC address in the packet with the recorded bridge MAC address. If the two bridge MAC addresses are the same, the commander determines that the member still exists in the network. If the commander does not receive a response packet from a member within 150 seconds, the commander determines that the member is offline. Then, the commander sets the status of the member to offline.

Manual SmartMC network establishment

You can log in to the Web interface of the commander, and enter the IP address, username, and password of the members to manually add them to the network. The members can join the network without exchanging SmartMC packets with the commander. For more information, see *Comware 7 Web-Based Products User Guide*.

After you specify the information of a member on the commander, the commander performs the following operations to add the member to the network:

- Verify that the member can be accessed through Telnet.
- Obtain basic member information, including LLDP neighbor information through NETCONF.
- Obtain hardware information through SNMP Get operations.

SmartMC features

Bulk configuration deployment for members

This feature allows you to deploy multiple command lines to members from the commander, eliminating the need to log in to members and configure the command one by one.

The procedure for bulk configuration deployment is as follows:

1. The commander acts as a Telnet client and establishes Telnet connections to the members.

2. The commander deploys a batch file to the members through Telnet connections. The batch file is created on the commander and contains command lines to be deployed.
3. The members run the command lines in the file.

Bulk configuration deployment for ports connecting APs and IP phones

This feature is designed to automatically detect the connection of APs and IP phones, and to automatically distribute configurations in bulk to the access ports. This simplifies and accelerates the process of configuring network devices, providing network administrators with an efficient management method.

The working mechanism of the bulk configuration deployment function is as follows:

1. Create batch files: The network administrator creates and binds command line batch files for APs and IP phones through the Web interface.
2. Device access: APs or IP phones connect to the SmartMC network through a TC.
3. Configuration deployment: Once the TM detects the connection of an AP or IP phone using the LLDP protocol, it sends the configurations from the corresponding command line batch file to the access port of the AP or IP phone, thus achieving automated configuration for the APs and IP phones.

Configuration file backup

You can use the following methods to back up the next-startup configuration file on the commander and members:

- **Automatic backup**—Enable this feature for the commander and all members in the network to immediately perform a backup. After that, the commander and members back up the configuration file at a user-specified interval.
- **Manual backup**—Manually trigger a backup on the commander or the specified members or SmartMC groups.

To back up the configuration file on a member, the commander instructs the member by unicasting a SmartMC packet. When a member receives the packet, it saves the running configuration to the next-startup configuration file and uploads the file to the file server.

Startup software and configuration file upgrade

This feature enables users to upgrade startup software and the configuration file of member devices from the commander.

Before upgrade, you must upload the upgrade files from the commander to the file server and specify the upgrade files on the file server for the members to download.

The procedure for startup software and configuration file upgrade is as follows:

1. The commander instructs the members (or SmartMC group) to download the upgrade files from the file server.
2. The members download the upgrade files from the file server.
3. The members upgrade the startup software and configuration file as follows:
    - **Startup software upgrade**—Uses the boot loader method to perform an upgrade. The members might be restarted during the upgrade process.
    - **Configuration file upgrade**—Replaces the current configuration file with the upgrade configuration file. The members will not be restarted during the upgrade process.

Faulty member replacement

You can use the following methods to replace a faulty member:

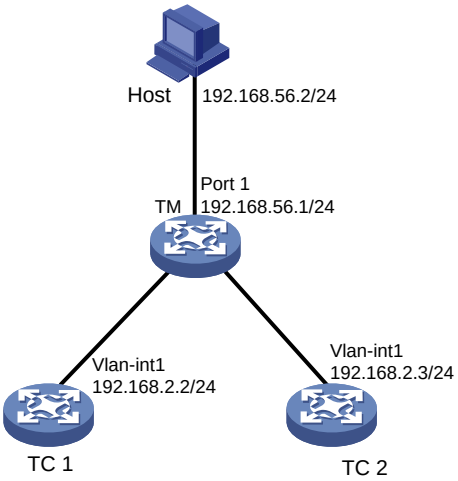
- **Automatic replacement**—Enables the commander to record the positions of all members in the topology for replacement. When the commander discovers that the new member has physically replaced the faulty member, it compares the new member with the faulty one. The commander performs a replacement if the following requirements are met:
    - The new member is deployed at the same topological position as the faulty one.

- The models of the new member and faulty member are the same.

  The commander then instructs the new member to download the configuration file of the faulty member from the file server. After downloading the configuration file, the new member runs the configuration file to complete the replacement.

- **Manual replacement**—After the faulty member is physically replaced, you manually trigger a configuration replacement. The new member will download the configuration file of the faulty member from the file server and run the file to complete the replacement.

Outgoing interface for a SmartMC network



The outgoing interface feature allows hosts connecting to an outgoing interface to access all the members in a SmartMC network. You can configure multiple outgoing interfaces for a SmartMC network.

As shown in Figure 2, the host is connected to port 1 on the TM and TC 1 and TC 2 are in a different network segment than the host. The host can access the Web interface of the TM but cannot access the Web interface of any member.

If port 1 on the TM is configured as the outgoing interface, the system mirrors the IP address of each member to a new address. The new address contains the IP address of the outgoing interface and the port number assigned by the commander to the member in the format of *IP address*:*Port number*. This enables the host to access the Web interfaces of members from the Web interface of the TM.

To access the Web interface of a member, enter the Web interface of the commander, and click **Visibility** from the navigation pane. Then, click the **Topology** tab, select the target member, and click **Login to Web interface**.

Figure 2 SmartMC network

Automatic link aggregation

Automatic link aggregation automatically bundles multiple physical Ethernet links between two members into one logical link, called an aggregate link. This feature provides increased link bandwidth and improved link reliability.

NOTE:

- Automatic link aggregation cannot be performed between the commander and a member, or between a member and a device outside the SmartMC network. You can aggregate the links between the commander and a member manually. For more information about manual link aggregation, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.
- If a member enabled with automatic link aggregation joins a SmartMC network whose commander is disabled with the aggregation feature, the feature will be disabled for the member as well. This might affect service traffic forwarding on the member.

VLAN creation for members

To simplify configuration and management, you can create a VLAN for members. Then, all access ports on a member that are not connected to other members or the commander are assigned to the VLAN.

If a member has access ports that are connected to offline devices, you must remove the offline devices before creating a VLAN for the member.

The VLAN creation fails for a member if one or more access ports cannot be assigned to the VLAN. If the VLAN creation fails, the VLAN memberships for the access ports are restored to the state before the VLAN was created.

The failure to create a VLAN for a member does not affect the VLAN creation for other members.

Resource monitoring

Resource monitoring allows you to view CPU usage, memory usage, temperature information,

You can view the usage and temperature information on the commander

Restrictions and guidelines: SmartMC configuration

Only users with the network-admin role can configure SmartMC. For more information about user roles, see RBAC in *Fundamentals Configuration Guide*.

A SmartMC network is established in VLAN 1. For the network to work correctly, do not configure security settings in VLAN 1.

You need to enable SmartMC on both the commander and members and perform all the other SmartMC tasks only on the commander.

SmartMC tasks at a glance

To configure SmartMC, perform the following tasks:

1. Enabling SmartMC
2. Specifying a file server

   This task is required for configuring automatic configuration file backup, replacing faulty members, and upgrading the startup software and configuration file on members.
3. (Optional.) Configuring an outgoing interface for the SmartMC network
4. (Optional.) Enabling automatic Ethernet link aggregation
5. (Optional.) Modifying the password of the default user for members
6. Creating a SmartMC group

   This task is required for upgrading the startup software and configuration file on members and deploying a batch file to a SmartMC group.
7. (Optional.) Deploying and managing configuration
   - Creating a VLAN for members
   - Deploying a batch file to members
   - Configuring a batch file for ports connecting APs or IP phones
   - Backing up configuration files
8. (Optional.) Monitoring and maintaining the SmartMC network
   - Configuring resource monitoring
   - Upgrading the startup software and configuration file on members

- Managing the network topology
- Replacing faulty members

Prerequisites for SmartMC

Before you configure SmartMC, perform the following tasks on the commander and members:

- Enable the Telnet service, and configure scheme authentication for VTY user lines. For information about Telnet service and VTY user lines, see CLI login configuration in *Fundamentals Configuration Guide*.
- Configure a local user.
  - Specify the username and password.
    - On the commander, make sure the username and password are the same as the username and password configured by using the **smartmc tm username** *username* **password** { **cipher** | **simple** } *string* **enable** command.
    - On a member, set both the username and password to **admin**, and execute the **password-control length 4**, **password-control composition type-number 1 type-length 1**, and **undo password-control complexity user-name check** commands to lower the password complexity requirements.

      This is because SmartMC requires that the commander use username **admin** and password **admin** to communicate with members, which does not meet the default password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

      After the SmartMC network is established, you can increase the password complexity requirements and use the **smartmc tc password** command to modify the username and password.
  - Specify the Telnet, HTTP, and HTTPS services for the user.
  - Set the RBAC role of the local user to network-admin.

  For information about local users, see AAA configuration in *Security Configuration Guide*. For information about user roles, see RBAC configuration in *Fundamentals Configuration Guide*.
- Enable NETCONF over SOAP over HTTP. For information about NETCONF over SOAP, see NETCONF configuration in *Network Management and Monitoring Configuration Guide*.
- Enable LLDP globally. For information about LLDP, see *Layer 2—LAN Switching Configuration Guide*.
- To manage the commander and members through a Web interface, you must enable the HTTP and HTTPS services, and set the service type to HTTP and HTTPS for the local user. For information about Web login, HTTP, and HTTPS, see *Fundamentals Configuration Guide*.
- To manually establish a SmartMC network, you must configure the **snmp-agent community read public** and **snmp-agent sys-info version v2c** commands on the members. For information about SNMP, see *Network Management and Monitoring Configuration Guide*.

Enabling SmartMC

About this task

Enable this feature on both the commander and members to enable management of members from the commander.

Restrictions and guidelines

A SmartMC network must have one and only one commander.

If you change the role of the commander to member or disable SmartMC on the commander, all SmartMC settings in its running configuration will be cleared.

SmartMC fails to be enabled if ACL resources are insufficient. If ACL resources are insufficient, use the **undo acl** command to delete unnecessary ACLs and then enable SmartMC. You can execute the **display acl** command to view ACL configuration and match statistics. For more information about ACLs, see *ACL and QoS Configuration Guide*.

SmartMC fails to be enabled if ports 80 and 443 have been used.

If you execute the **smartmc enable** command multiple times, the most recent configuration takes effect. You can execute the command to change the device role or the password.

Procedure

1. Enter system view.

   system-view

2. Enable SmartMC and set the device role.

   smartmc { **tc** | **tm username** *username* **password** { **cipher** | **simple** } *string* } **enable**

   By default, SmartMC is disabled.

Specifying a file server

About this task

In a SmartMC network, a file server is used to store the following files:

- Upgrade startup software files and upgrade configuration file for members.
- Backup configuration files of the commander and members.

The system supports using an FTP or SFTP server as the file server. For information about FTP servers, see configuring FTP in *Fundamentals Configuration Guide*. For information about SFTP servers, see configuring SSH in *Security Configuration Guide*.

Restrictions and guidelines

You can use the following methods to specify a file server:

- Specify the IP address of a file server.
- Specify the IP address of the commander. The commander will act as a file server.

To configure the commander to act as a file server, make sure the commander has enough storage space for storing the files required by members.

To use an independent file server, connect the file server to the commander instead of the members as a best practice. The file server uses VLAN 1 to communicate with the SmartMC network. If you connect the file server to members, creating a VLAN for members will assign member interfaces connecting to the file server to the created VLAN, causing file server disconnection. For more information about member VLAN creation, see "Creating a VLAN for members."

Procedure

1. Enter system view.

   system-view

2. Specify a file server.

   smartmc { **ftp-server** | **sftp-server** } { *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port*] [**vpn-instance** *vpn-instance-name*] [**directory** *directory*] **username** *username* **password** { **cipher** | **simple** } *string*

   By default, no file server is specified.

Configuring an outgoing interface for the SmartMC network

Restrictions and guidelines

VLAN-interface 1 cannot be used as an outgoing interface, because the SmartMC network is established in VLAN 1.

If you specify a VLAN interface as the outgoing interface, the system issues the **service slot** *slot-number* command to the outgoing interface and VLAN-interface 1. The *slot-number* argument represents the member ID of the master device. If you remove the outgoing interface configuration, the **service slot** *slot-number* configuration remains, and you can modify the configuration manually as needed.

For more information about the **service** command, see VLAN commands in *Layer 2—LAN Switching Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN interface view.
   interface vlan *interface-number*
3. Configure the interface as an outgoing interface.
   smartmc outbound
   By default, no interface is used as an outgoing interface.

Enabling automatic Ethernet link aggregation

Restrictions and guidelines

Enabling or disabling automatic link aggregation might cause network flapping, and the members might go offline for a short period of time.

Procedure

1. Enter system view.
   system-view
2. Enable automatic Ethernet link aggregation.
   smartmc auto-link-aggregation enable
   By default, automatic Ethernet link aggregation is disabled.

Modifying the password of the default user for members

About this task

During SmartMC network establishment, the commander uses the default username and password to establish NETCONF sessions to members automatically added to the network. The default username and password of the members for NETCONF session establishment are **admin** and **admin**.

To enhance security, you can perform this task to change the password for the default user **admin** of the members after the commander adds the members to the network.

Restrictions and guidelines

Do not modify the password for members that are manually added to the SmartMC network. If you modify the password for a manually added member, you will not be able to manage that member from the commander.

You can use the **display smartmc tc verbose** command to identify the method used to add the members.

Procedure

1. Enter system view.
   system-view
2. Modify the password of the default user for members.
   smartmc tc password [**cipher**] *string*

Creating a SmartMC group

About this task

This feature allows you to create a SmartMC group on the commander and add members to the group. When you perform the following operations, you can specify a SmartMC group to apply the operations to all members in the group:

- Startup software upgrade.
- Configuration file upgrade.
- Configuration deployment.

Procedure

1. Enter system view.
   system-view
2. Create a SmartMC group and enter its view.
   smartmc group *group-name*
3. (Optional.) Display predefined device types.
   match device-type ?
4. Set a match criterion.
   match { **device-type** *device-type* | **ip-address** *ip-address* { *ip-mask-length* | *ip-mask* } | **mac-address** *mac-address mac-mask-length* }
   By default, no match criterion is set.
5. If the device type of the members is not predefined on the commander, perform the following tasks to manually define the device type on the commander:
   a. Return to system view.
      quit
   b. Define a device type on the commander.
      smartmc tc sysoid *sysoid* **device-type** *device-type*
      To obtain the SYSOID of a member, execute the **display smartmc tc verbose** command.
      You cannot define a predefined member type as another type.

Creating a VLAN for members

Restrictions and guidelines

If you perform this task multiple times to create a VLAN for members, the most recent configuration takes effect.

Procedure

1. Enter system view.

   system-view

2. Creating a VLAN for members and assign access ports on the members to the VLAN.

   smartmc vlan *vlan-id* { **group** *group-name-list* | **tc** *tc-id-list* }

Deploying a batch file to members

1. Execute the following command in user view to create a batch file and edit the command lines to be deployed to members.

   create batch-file *cmd-filename*

   Each command occupies a line in the batch file. When you finish editing, enter a percent sign (%) to return to user view.

   Make sure the command lines that you enter are correct because the system does not verify whether the command lines are correct.

2. Enter system view.

   system-view

3. Deploy the batch file to a list of members or SmartMC groups.

   smartmc batch-file *cmd-filename* **deploy** { **group** *group-name-list* | **tc** *tc-id-list* }

Configuring a batch file for ports connecting APs or IP phones

Restrictions and guidelines

All commands in the batch file must be commands used in interface view.

The size of the batch file cannot exceed 8190 characters.

Make sure the file name is correct when specifying the batch file because the system does not verify whether the file name is correct. After specifying the batch file, do not delete the file or rename the file.

Content changes of a batch file and binding of a different batch file on the device affect only APs and IP phones that come online afterwards. The APs and IP phones that are already connected are not affected.

Procedure

1. (Optional.) Execute the following command in user view to create a batch file and edit the command lines to be deployed to members.

   create batch-file *cmd-filename*

   Each command occupies a line in the batch file. When you finish editing, enter a percent sign (%) to return to user view.

Make sure the command lines that you enter are correct because the system does not verify whether the command lines are correct.

2. Enter system view.

   system-view

3. Enable batch file deployment.

   smartmc batch-file-apply enable

   By default, batch file deployment is enabled.

4. Specify the batch file for ports connecting APs or IP phones.

   smartmc batch-file *batch-file-name* **apply** { **ap** | **phone** }

   To disable the commander from deploying batch files to ports, execute the **undo smartmc batch-file-apply enable** command to disable batch file deployment.

Backing up configuration files

About this task

Perform this task to back up the configuration file of the commander or the specified members. Configuration files automatically backed up to the file server are named in the format of *device_bridge_MAC_address*_**backup.cfg**.

Restrictions and guidelines

When you change the commander in the SmartMC network, make sure the backup configuration file of the original commander on the file server is deleted. If the file still exists, the new commander might download the file and run the settings. This will cause a conflict in the network.

The maximum number of members that can perform automatic configuration at the same time is limited by the performance of the file server. If automatic configuration backup fails, set the maximum number of members to a smaller value.

Prerequisites

Before performing this task, you must specify a file server (see "Specifying a file server").

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of members that can perform configuration file backup at the same time.

   smartmc backup configuration max-number *max-number*

   By default, a maximum of five members can perform automatic configuration backup at the same time.

3. Back up configuration files.

   Choose one option as needed:

   - Enable automatic configuration file backup and set the backup interval.

     smartmc backup startup-configuration interval *interval-time*

     By default, automatic configuration file backup is disabled.

   - Manually back up the configuration file on the commander or the specified members.

     smartmc backup configuration { **group** *group-name-list* | **tc** [*tc-id-list*] }

     TC ID 0 represents the commander.

Configuring resource monitoring

1. Enter system view.

   system-view
2. Set the interval for the commander to obtain resource monitoring information.

   smartmc resource-monitor interval *interval*

   The default setting is 1 minute.
3. Set the aging time for resource monitoring information.

   smartmc resource-monitor max-age *max-age*

   The default setting is 24 hours.
4. Enable resource monitoring.

   smartmc resource-monitor [**cpu** | **memory** | **temperature**]* [**group** *group-name-list* | **tc** { *tc-id-list* | **mac-address** *mac-address* } | **tm**]

   By default, resource monitoring is disabled.

   If you do not specify a resource type, this command enables resource monitoring for all resource types.

   If you do not specify a device to monitor (member or commander), this command enables resource monitoring on the commander and all members.

Upgrading the startup software and configuration file on members

About upgrading the startup software and configuration file on members

You can use the following methods to upgrade the startup software and configuration file on members:

- Schedule an upgrade by specifying an upgrade time or upgrade delay.
- Upgrade immediately by not specifying an upgrade time or upgrade delay.

Restrictions and guidelines for startup software and configuration file upgrade

A member can perform only one upgrade task at a time.

An immediate upgrade cannot be cancelled. If you specify a delay time or upgrade time to perform a scheduled upgrade, the upgrade operation can be cancelled by using the **undo smartmc upgrade** command before it starts.

Prerequisites

Before performing this task, you must specify a file server (see "Specifying a file server").

Upgrading the startup software and configuration file on members

Upgrading the startup software and configuration file in one step

1. Enter system view.

   system-view

2. Upgrade the startup software on members in one step.

   smartmc upgrade boot-loader tc { *tc-id-list* { **boot** *boot-filename* **system** *system-filename* | **file** *ipe-filename* } }&<1-40> [**delay** *delay-time* | **time** *in-time*]

   CAUTION:

   Upgrading the startup software might interrupt services. Before the upgrade, make sure service operation will not be affected.

3. Upgrade the configuration file on members in one step.

   smartmc upgrade startup-configuration tc { *tc-id-list cfg-filename* }&<1-40> [**delay** *delay-time* | **time** *in-time*]

   CAUTION:

   To ensure correct device operation, make sure the contents of the configuration file are correct. After the upgrade, the configuration in the new file will become the running configuration.

Configuring startup software and configuration file upgrade step by step

1. Enter system view.

   system-view

2. Configure startup software upgrade for members step by step:

   a. Specify the upgrade startup software files.

      smartmc tc *tc-id* **boot-loader** { *ipe-filename* | **boot** *boot-filename* **system** *system-filename* }

   b. Upgrade the startup software on members.

      smartmc upgrade boot-loader tc *tc-id-list*

   CAUTION:

   Upgrading the startup software might interrupt services. Before the upgrade, make sure service operation will not be affected.

3. Configure configuration file upgrade for members step by step:

   a. Specify the upgrade configuration file.

      smartmc tc *tc-id* **startup-configuration** *cfg-filename*

   b. Upgrade the configuration file on members.

      smartmc upgrade startup-configuration tc *tc-id-list*

   CAUTION:

   To ensure correct device operation, make sure the contents of the configuration file are correct. After the upgrade, the configuration in the new file will become the running configuration.

Upgrading the startup software and configuration file on all members in SmartMC groups

Upgrading the startup software and configuration file in one step

1. Enter system view.

   system-view

2. Upgrade the startup software on all members in SmartMC groups in one step.

   smartmc upgrade boot-loader group { *group-name-list* [**boot** *boot-filename* **system** *system-filename* | **file** *ipe-filename*] }&<1-40> [**delay** *minutes* | **time** *in-time*]

   CAUTION:

   Upgrading the startup software might interrupt services. Before the upgrade, make sure service operation will not be affected.

3. Upgrade the configuration file on all members in SmartMC groups in one step.

   smartmc upgrade startup-configuration group { *group-name-list* **file** *cfg-filename* }&<1-40> [**delay** *minutes* | **time** *in-time*]

   CAUTION:

   To ensure correct device operation, make sure the contents of the configuration file are correct. After the upgrade, the configuration in the new file will become the running configuration.

Configuring startup software and configuration file upgrade step by step

1. Enter system view.

   system-view

2. Enter SmartMC group view.

   smartmc group *group-name*

3. Specify the upgrade startup software files for the SmartMC group.

   boot-loader file { *ipe-filename* | **boot** *boot-filename* **system** *system-filename* }

   By default, no upgrade startup software files are specified for a SmartMC group.

4. Specify the upgrade configuration file for the SmartMC group.

   startup-configuration *cfgfile*

   By default, no upgrade configuration file is specified for a SmartMC group.

5. Return to system view.

   quit

6. Upgrade the startup software and configuration file on all members in the SmartMC group.

   Choose one option as needed:

   - Upgrade the startup software.

     smartmc upgrade boot-loader group *group-name-list* [**delay** *minutes* | **time** *in-time*]

     CAUTION:

     Upgrading the startup software might interrupt services. Before the upgrade, make sure service operation will not be affected.

- Upgrade the configuration file.

  smartmc upgrade startup-configuration group *group-name-list* [**delay** *minutes* | **time** *in-time*]

CAUTION:

To ensure correct device operation, make sure the contents of the configuration file are correct. After the upgrade, the configuration in the new file will become the running configuration.

Managing the network topology

Refreshing the network topology

About this task

You can use the following methods to refresh the network topology:

- **Automatic topology refresh**—Specify the refresh interval to allow the commander to refresh the network topology periodically.
- **Manual topology refresh**—Execute the **smartmc topology-refresh** command to manually refresh the network topology.

Restrictions and guidelines

The topology refresh time depends on the number of members in the network.

Procedure

Choose one option as needed:

- Manually refresh the network topology in any view.

  smartmc topology-refresh
- Configure automatic network topology refresh.
  1. Enter system view.

     system-view
  2. Set the automatic topology refresh interval.

     smartmc topology-refresh interval *interval*

     By default, the automatic topology refresh interval is 60 seconds.

Saving the network topology

About this task

This task allows you to save the current network topology to the **topology.dba** file in the flash memory. After the commander reboots, it uses the **topology.dba** file to restore the network topology.

Procedure

1. Enter system view.

   system-view
2. Save the network topology.

   smartmc topology-save

Replacing faulty members

Restrictions and guidelines

Make sure the new member for replacement and the faulty member have the same neighbor relationship and device model.

Make sure the new member has a different member ID than all the members in the SmartMC network, including offline members. Faulty members are considered offline.

To automatically replace a faulty member, first enable automatic replacement, and then install the new member at the location where the faulty member was installed and connect all cables.

To manually replace a faulty member, first install the new member at the location where the faulty member was installed, connect all cables, and then execute the manual replacement command.

Prerequisites

Before you replace a faulty member, specify a file server (see "Specifying a file server").

Procedure

1. Enter system view.
   system-view
2. Replace faulty members.
   Choose one option as needed:
   - Enable automatic faulty member replacement.
     smartmc auto-replace enable
     By default, automatic faulty member replacement is disabled.
   - Manually replace a faulty member.
     smartmc replace tc *tc-id1* **faulty-tc** *tc-id2*

Display and maintenance commands for SmartMC

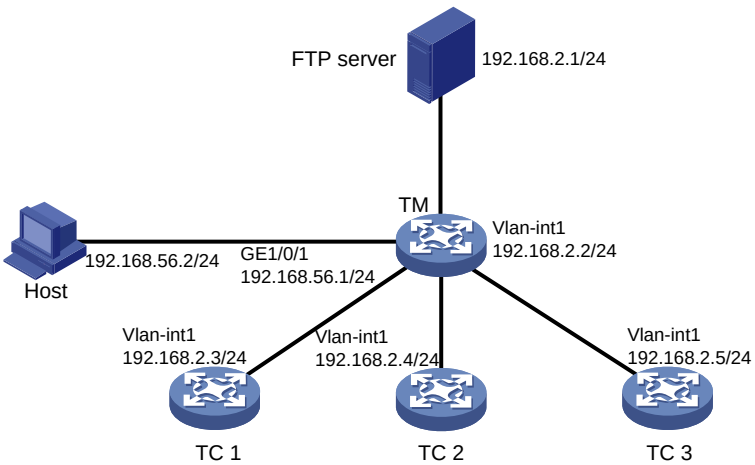
Execute **display** commands in any view.

Task	Command
Display the backup status on members.	**display smartmc backup configuration status**
Display the batch file execution results.	**display smartmc batch-file status** [**ap** | **last** *number* | **phone**]
Display SmartMC configuration.	**display smartmc configuration**
Display connections between the devices in the SmartMC network.	**display smartmc device-link**
Display SmartMC group information.	**display smartmc group** [*group-name*] [**verbose**]
Display the faulty member replacement status.	**display smartmc replace status**
Display resource monitoring information.	**display smartmc resource-monitor** [**cpu** | **memory** | **temperature**] * [**tc** *tc-id* | **tm**]
Display resource monitoring configuration.	**display smartmc resource-monitor configuration**

Task	Command
Display member information.	**display smartmc tc** [*tc-id*][**verbose**]
Display log information in the log buffer on a member.	**display smartmc tc** *tc-id* **log buffer** [**module** *module-name* [**mnemonic** *mnemonic-value*]]
Display restart log information for a member.	**display smartmc tc** *tc-id* **log restart**
Display VLAN creation results for members.	**display smartmc vlan**
Display member upgrade status.	**display smartmc upgrade status**

SmartMC configuration examples

Example: Configuring SmartMC



Network configuration

As shown in Figure 3, member 1, member 2, and member 3 belong to the same device type: S5170-EI series. The IP address of the file server is 192.168.2.1. The username and password for accessing the file server are **admin** and **hello12345**, respectively.

Perform the following tasks to establish a SmartMC network and upgrade the configuration file on the members:

1. Configure the commander and members to automatically establish a SmartMC network.
2. Configure interface GigabitEthernet 1/0/1 as the outgoing interface for the SmartMC network.
3. Create a SmartMC group and add the members to the group.
4. Upgrade the configuration file on all members in the SmartMC group.
5. Save configuration file **startup.cfg** on the file server.

Figure 3 Network diagram

Procedure

1. Configure TC 1:

   # Configure VLAN-interface 1.

   ```
   <TC1> system-view
   [TC1] interface vlan-interface 1
   ```

```
[TC1-Vlan-interface1] ip address 192.168.2.3 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to **tc**.

```
[TC1] smartmc tc enable
```

2. Configure TC 2 and TC 3 in the same way TC 1 is configured. (Details not shown.)

3. Configure the TM:

Configure GigabitEthernet 1/0/1.

```
<TM> system-view
[TM] interface gigabitethernet 1/0/1
[TM-GigabitEthernet1/0/1] port link-mode route
[TM-GigabitEthernet1/0/1] ip address 192.168.52.2 24
[TM-GigabitEthernet1/0/1] quit
```

Configure VLAN-interface 1.

```
[TM] interface vlan-interface 1
[TM-Vlan-interface1] ip address 192.168.2.2 24
[TM-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TM] ip http enable
[TM] ip https enable
```

Enable the Telnet service.

```
[TM] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and the password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

Specify GigabitEthernet 1/0/1 as the outgoing interface.

```
[TM] interface gigabitethernet 1/0/1
[TM-GigabitEthernet1/0/1] smartmc outbound
[TM-GigabitEthernet1/0/1] quit
```

Set the file server IP address, username, and plaintext password to 192.168.2.1, **admin**, and **hello12345**, respectively.

```
[TM] smartmc ftp-server 192.168.2.1 username admin password simple hello12345
```

Create SmartMC group **S1** and enter its view.

```
[TM] smartmc group S1
```

Create an IP address match criterion to add all members in the specified network segment to SmartMC group **S1**.

```
[TM-smartmc-group-S1] match ip-address 192.168.2.0 24
```

Specify the upgrade configuration file **startup.cfg** for SmartMC group **S1**.

```
[TM-smartmc-group-S1] startup-configuration startup.cfg
[TM-smartmc-group-S1] quit
```

Upgrade the configuration file on all members in SmartMC group **S1**.

```
[TM] smartmc upgrade startup-configuration group S1 file startup.cfg
```

Verifying the configuration

Display brief information about all members after the SmartMC network is established.

```
[TM] display smartmc tc
    TCID DeviceType Sysname  IpAddress       MacAddress     Status   Version
    1    S5170-EI   TC1      192.168.2.3     201c-e7c3-0300 Normal   7.1.070 ESS 1103
    2    S5170-EI   TC2      192.168.2.4     201c-e7c3-0301 Normal   7.1.070 ESS 1103
    3    S5170-EI   TC3      192.168.2.5     201c-e7c3-0302 Normal   7.1.070 ESS 1103
```

Display the configuration file upgrade status on the members.

```
<TM> display smartmc upgrade status
ID    IpAddress        MacAddress      Status      UpdateTime        UpdateFile
1     192.168.2.3      201c-e7c3-0300  Finished    Immediately       startup.cfg
2     192.168.2.4      201c-e7c3-0301  Finished    Immediately       startup.cfg
```

```
3     192.168.2.5      201c-e7c3-0302  Finished    Immediately       startup.cfg
```

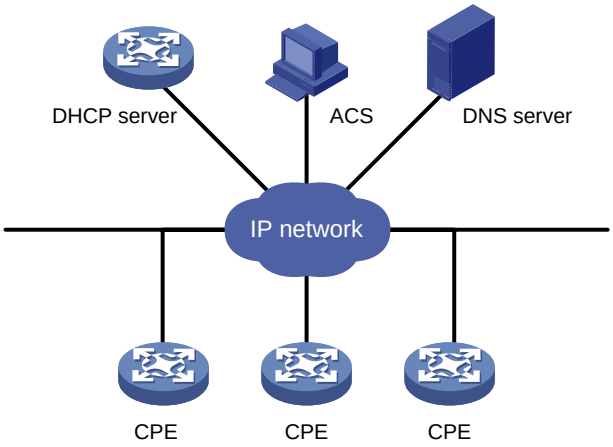
Configuring CWMP

About CWMP



CPE WAN Management Protocol (CWMP), also called "TR-069," is a DSL Forum technical specification for remote management of network devices.

The protocol was initially designed to provide remote autoconfiguration through a server for large numbers of dispersed end-user devices in a network. CWMP can be used on different types of networks, including Ethernet.

CWMP network framework

Figure 1 shows a basic CWMP network framework.

Figure 1 CWMP network framework

A basic CWMP network includes the following network elements:

- **ACS**—Autoconfiguration server, the management device in the network.
- **CPE**—Customer premises equipment, the managed device in the network.
- **DNS server**—Domain name system server. CWMP defines that the ACS and the CPE use URLs to identify and access each other. DNS is used to resolve the URLs.
- **DHCP server**—Assigns ACS attributes along with IP addresses to CPEs when the CPEs are powered on. DHCP server is optional in CWMP. With a DHCP server, you do not need to configure ACS attributes manually on each CPE. The CPEs can contact the ACS automatically when they are powered on for the first time.

The device is operating as a CPE in the CWMP framework.

Basic CWMP functions

You can autoconfigure and upgrade CPEs in bulk from the ACS.

Autoconfiguration

You can create configuration files for different categories of CPEs on the ACS. Based on the device models and serial numbers of the CPEs, the ACS verifies the categories of the CPEs and issues the associated configuration to them.

The following are methods available for the ACS to issue configuration to the CPE:

- Transfers the configuration file to the CPE, and specifies the file as the next-startup configuration file. At a reboot, the CPE starts up with the ACS-specified configuration file.
- Runs the configuration in the CPE's RAM. The configuration takes effect immediately on the CPE. For the running configuration to survive a reboot, you must save the configuration on the CPE.

CPE software management

The ACS can manage CPE software upgrade.

When the ACS finds a software version update, the ACS notifies the CPE to download the software image file from a specific location. The location can be the URL of the ACS or an independent file server.

If the CPE successfully downloads the software image file and the file is validated, the CPE notifies the ACS of a successful download. If the CPE fails to download the software image file or the file is invalidated, the CPE notifies the ACS of an unsuccessful download.

Data backup

The ACS can require the CPE to upload a configuration file or log file to a specific location. The destination location can be the ACS or a file server.

CPE status and performance monitoring

The ACS can monitor the status and performance of CPEs. Table 1 shows the available CPE status and performance objects for the ACS to monitor.

Table 1 CPE status and performance objects available for the ACS to monitor

Category	Objects	Remarks
Device information	Manufacturer ManufacturerOUI SerialNumber HardwareVersion SoftwareVersion	N/A
Operating status and information	DeviceStatus UpTime	N/A
Configuration file	ConfigFile	Local configuration file stored on CPE for upgrade. The ACS can issue configuration to the CPE by transferring a configuration file to the CPE or running the configuration in CPE's RAM.
CWMP settings	ACS URL	URL address of the ACS to which the CPE initiates a CWMP connection. This object is also used for main/backup ACS switchover.
	ACS username ACS password	When the username and password of the ACS are changed, the ACS changes the ACS username and password on the CPE to the new username and password. When a main/backup ACS switchover occurs, the main ACS also changes the ACS username and password to the backup ACS username and password.
	PeriodicInformEnable	Whether to enable or disable the periodic Inform feature.
	PeriodicInformInterval	Interval for periodic connection from the CPE

Category	Objects	Remarks
		to the ACS for configuration and software update.
	PeriodicInformTime	Scheduled time for connection from the CPE to the ACS for configuration and software update.
	ConnectionRequestURL (CPE URL)	N/A
	ConnectionRequestUsername (CPE username) ConnectionRequestPassword (CPE password)	CPE username and password for authentication from the ACS to the CPE.

How CWMP works

RPC methods

CWMP uses remote procedure call (RPC) methods for bidirectional communication between CPE and ACS. The RPC methods are encapsulated in HTTP or HTTPS.

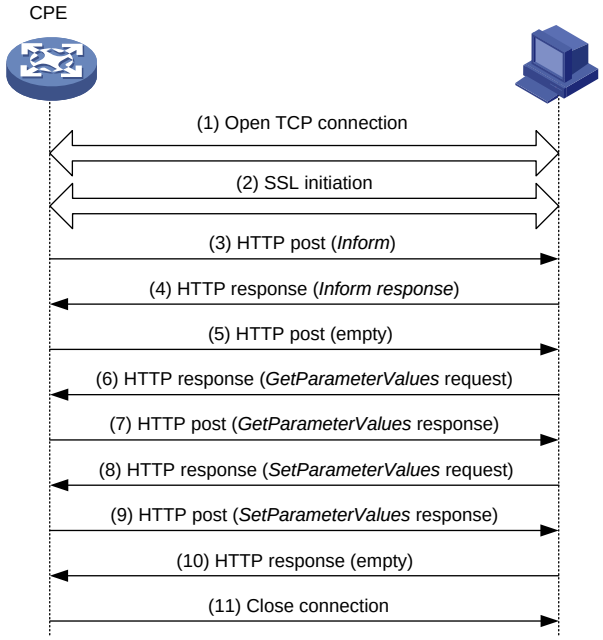
Table 2 shows the primary RPC methods used in CWMP.

Table 2 RPC methods

RPC method	Description
Get	The ACS obtains the values of parameters on the CPE.
Set	The ACS modifies the values of parameters on the CPE.
Inform	The CPE sends an Inform message to the ACS for the following purposes: • Initiates a connection to the ACS. • Reports configuration changes to the ACS. • Periodically updates CPE settings to the ACS.
Download	The ACS requires the CPE to download a configuration or software image file from a specific URL for software or configuration update.
Upload	The ACS requires the CPE to upload a file to a specific URL.
Reboot	The ACS reboots the CPE remotely for the CPE to complete an upgrade or recover from an error condition.

Autoconnect between ACS and CPE

The CPE automatically initiates a connection to the ACS when one of the following events occurs:



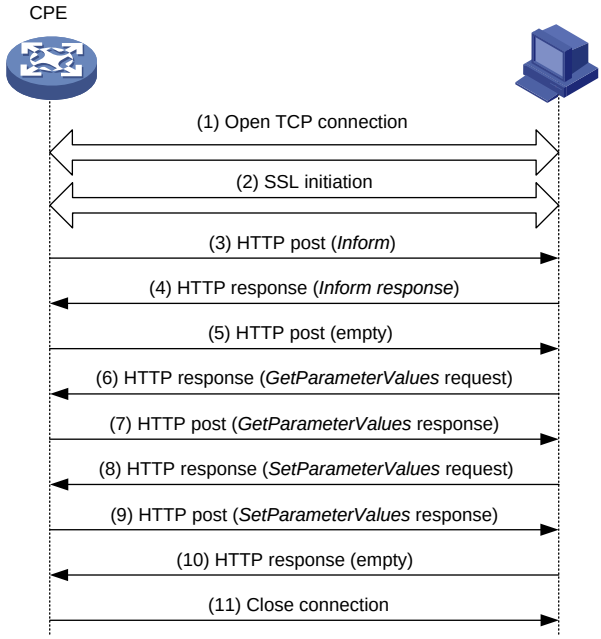
- ACS URL change. The CPE initiates a connection request to the new ACS URL.
- CPE startup. The CPE initiates a connection to the ACS after the startup.
- Timeout of the periodic Inform interval. The CPE re-initiates a connection to the ACS at the Inform interval.
- Expiration of the scheduled connection initiation time. The CPE initiates a connection to the ACS at the scheduled time.

CWMP connection establishment

Step 1 through step 5 in Figure 2 show the procedure of establishing a connection between the CPE and the ACS.

1. After obtaining the basic ACS parameters, the CPE initiates a TCP connection to the ACS.
2. If HTTPS is used, the CPE and the ACS initialize SSL for a secure HTTP connection.
3. The CPE sends an Inform message in HTTPS to initiate a CWMP session.
4. After the CPE passes authentication, the ACS returns an Inform response to establish the session.
5. After sending all requests, the CPE sends an empty HTTP post message.

Figure 2 CWMP connection establishment



Main/backup ACS switchover

Typically, two ACSs are used in a CWMP network for consecutive monitoring on CPEs. When the main ACS needs to reboot, it points the CPE to the backup ACS. Step 6 through step 11 in Figure 3 show the procedure of a main/backup ACS switchover.

1. Before the main ACS reboots, it queries the ACS URL set on the CPE.
2. The CPE replies with its ACS URL setting.
3. The main ACS sends a Set request to change the ACS URL on the CPE to the backup ACS URL.
4. After the ACS URL is modified, the CPE sends a response.
5. The main ACS sends an empty HTTP message to notify the CPE that it has no other requests.
6. The CPE closes the connection, and then initiates a new connection to the backup ACS URL.

Figure 3 Main and backup ACS switchover

Restrictions and guidelines: CWMP configuration

CWMP is available only in IPv4 networks. If you configure CWMP in an IPv6 network, the feature does not take effect.

You can configure ACS and CPE attributes from the CPE's CLI, the DHCP server, or the ACS. For an attribute, the CLI- and ACS-assigned values have higher priority than the DHCP-assigned value. The CLI- and ACS-assigned values overwrite each other, whichever is assigned later.

This document only describes configuring ACS and CPE attributes from the CLI and DHCP server. For more information about configuring and using the ACS, see ACS documentation.

CWMP tasks at a glance

To configure CWMP, perform the following tasks:

1. Enabling CWMP from the CLI

   You can also enable CWMP from a DHCP server.
2. Configuring ACS attributes
   a. Configuring the preferred ACS attributes
   b. (Optional.) Configuring the default ACS attributes from the CLI
3. Configuring CPE attributes
   a. Specifying an SSL client policy for HTTPS connection to ACS

      This task is required when the ACS uses HTTPS for secure access.
   b. (Optional.) Configuring ACS authentication parameters
   c. (Optional.) Configuring the provision code
   d. (Optional.) Configuring the CWMP connection interface
   e. (Optional.) Configuring autoconnect parameters
   f. (Optional.) Setting the close-wait timer

g. (Optional.) Enabling NAT traversal for the CPE

Enabling CWMP from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Enable CWMP.
   cwmp enable
   By default, CWMP is disabled.

Configuring ACS attributes

About ACS attributes

You can configure two sets of ACS attributes for the CPE: preferred and default.

- The preferred ACS attributes are configurable from the CPE's CLI, the DHCP server, and ACS.
- The default ACS attributes are configurable only from the CLI.

If the preferred ACS attributes are not configured, the CPE uses the default ACS attributes for connection establishment.

Configuring the preferred ACS attributes

Assigning ACS attributes from the DHCP server

The DHCP server in a CWMP network assigns the following information to CPEs:

- IP addresses for the CPEs.
- DNS server address.
- ACS URL and ACS login authentication information.

This section introduces how to use DHCP option 43 to assign the ACS URL and ACS login authentication username and password. For more information about DHCP and DNS, see *Layer 3—IP Services Configuration Guide*.

If the DHCP server is an H3C device, you can configure DHCP option 43 by using the **option 43 hex 01***length URL username password* command.

- *length*—A hexadecimal number that indicates the total length of the *length*, *URL*, *username*, and *password* arguments, including the spaces between these arguments. No space is allowed between the **01** keyword and the length value.
- *URL*—ACS URL.
- *username*—Username for the CPE to authenticate to the ACS.
- *password*—Password for the CPE to authenticate to the ACS.

NOTE:

The ACS URL, username and password must use the hexadecimal format and be space separated.

The following example configures the ACS address as **http://169.254.76.31:7547/acs**, username as **1234**, and password as **5678**:

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] option 43 hex
0127687474703A2F2F3136392E3235342E37362E33313A373534372F6163732031323334203536373 8
```

Table 3 Hexadecimal forms of the ACS attributes

Attribute	Attribute value	Hexadecimal form
Length	39 characters	27
ACS URL	http://169.254.76.31:7547/acs	687474703A2F2F3136392E3235342E37362E33313A373534372F61637320 **NOTE:** The two ending digits (20) represent the space.
ACS connect username	1234	3132333420 **NOTE:** The two ending digits (20) represent the space.
ACS connect password	5678	35363738

Configuring the preferred ACS attributes from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Configure the preferred ACS URL.
   cwmp acs url *url*
   By default, no preferred ACS URL has been configured.
4. Configure the username for authentication to the preferred ACS URL.
   cwmp acs username *username*
   By default, no username has been configured for authentication to the preferred ACS URL.
5. (Optional.) Configure the password for authentication to the preferred ACS URL.
   cwmp acs password { **cipher** | **simple** } *string*
   By default, no password has been configured for authentication to the preferred ACS URL.

Configuring the default ACS attributes from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Configure the default ACS URL.
   cwmp acs default url *url*
   By default, no default ACS URL has been configured.
4. Configure the username for authentication to the default ACS URL.
   cwmp acs default username *username*
   By default, no username has been configured for authentication to the default ACS URL.

5. (Optional.) Configure the password for authentication to the default ACS URL.

   cwmp acs default password { **cipher** | **simple** } *string*

   By default, no password has been configured for authentication to the default ACS URL.

Configuring CPE attributes

About CPE attributes

You can configure the following CPE attributes only from the CPE's CLI.

- CWMP connection interface.
- NAT traversal.
- Maximum number of connection retries.
- SSL client policy for HTTPS connection to ACS.

For other CPE attribute values, you can assign them to the CPE from the CPE's CLI or the ACS. The CLI- and ACS-assigned values overwrite each other, whichever is assigned later.

Specifying an SSL client policy for HTTPS connection to ACS

About this task

This task is required when the ACS uses HTTPS for secure access. CWMP uses HTTP or HTTPS for data transmission. When HTTPS is used, the ACS URL begins with **https://**. You must specify an SSL client policy for the CPE to authenticate the ACS for HTTPS connection establishment.

Prerequisites

Before you perform this task, first create an SSL client policy. For more information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Specify an SSL client policy.

   ssl client-policy *policy-name*

   By default, no SSL client policy is specified.

Configuring ACS authentication parameters

About this task

To protect the CPE against unauthorized access, configure a CPE username and password for ACS authentication. When an ACS initiates a connection to the CPE, the ACS must provide the correct username and password.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

cwmp

3. Configure the username for authentication to the CPE.

   cwmp cpe username *username*

   By default, no username has been configured for authentication to the CPE.

4. (Optional.) Configure the password for authentication to the CPE.

   cwmp cpe password { **cipher** | **simple** } *string*

   By default, no password has been configured for authentication to the CPE.

   The password setting is optional. You can specify only a username for authentication.

Configuring the provision code

About this task

The ACS can use the provision code to identify services assigned to each CPE. For correct configuration deployment, make sure the same provision code is configured on the CPE and the ACS. For information about the support of your ACS for provision codes, see the ACS documentation.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Configure the provision code.

   cwmp cpe provision-code *provision-code*

   The default provision code is **PROVISIONINGCODE**.

Configuring the CWMP connection interface

About this task

The CWMP connection interface is the interface that the CPE uses to communicate with the ACS. To establish a CWMP connection, the CPE sends the IP address of this interface in the Inform messages, and the ACS replies to this IP address.

Typically, the CPE selects the CWMP connection interface automatically. If the CWMP connection interface is not the interface that connects the CPE to the ACS, the CPE fails to establish a CWMP connection with the ACS. In this case, you need to manually set the CWMP connection interface.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Specify the interface that connects to the ACS as the CWMP connection interface.

   cwmp cpe connect interface *interface-type interface-number*

   By default, no CWMP connection interface is specified.

Configuring autoconnect parameters

About this task

You can configure the CPE to connect to the ACS periodically, or at a scheduled time for configuration or software update.

The CPE retries a connection automatically when one of the following events occurs:

- The CPE fails to connect to the ACS. The CPE considers a connection attempt as having failed when the close-wait timer expires. This timer starts when the CPE sends an Inform request. If the CPE fails to receive a response before the timer expires, the CPE resends the Inform request.
- The connection is disconnected before the session on the connection is completed.

To protect system resources, limit the number of retries that the CPE can make to connect to the ACS.

Configuring the periodic Inform feature

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Enable the periodic Inform feature.
   `cwmp cpe inform interval enable`
   By default, this function is disabled.
4. Set the Inform interval.
   `cwmp cpe inform interval` *`interval`*
   By default, the CPE sends an Inform message to start a session every 600 seconds.

Scheduling a connection initiation

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Schedule a connection initiation.
   `cwmp cpe inform time` *`time`*
   By default, no connection initiation has been scheduled.

Setting the maximum number of connection retries

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Set the maximum number of connection retries.
   `cwmp cpe connect retry` *`retries`*
   By default, the CPE retries a failed connection until the connection is established.

Setting the close-wait timer

About this task

The close-wait timer specifies the following:

- The maximum amount of time the CPE waits for the response to a session request. The CPE determines that its session attempt has failed when the timer expires.
- The amount of time the connection to the ACS can be idle before it is terminated. The CPE terminates the connection to the ACS if no traffic is sent or received before the timer expires.

Procedure

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Set the close-wait timer.
   `cwmp cpe wait timeout` *`seconds`*
   By default, the close-wait timer is 30 seconds.

Enabling NAT traversal for the CPE

About this task

For the connection request initiated from the ACS to reach the CPE, you must enable NAT traversal on the CPE when a NAT gateway resides between the CPE and the ACS.

The NAT traversal feature complies with RFC 3489 Simple Traversal of UDP Through NATs (STUN). The feature enables the CPE to discover the NAT gateway, and obtain an open NAT binding (a public IP address and port binding) through which the ACS can send unsolicited packets. The CPE sends the binding to the ACS when it initiates a connection to the ACS. For the connection requests sent by the ACS at any time to reach the CPE, the CPE maintains the open NAT binding. For more information about NAT, see *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Enable NAT traversal.
   `cwmp cpe stun enable`
   By default, NAT traversal is disabled on the CPE.

Display and maintenance commands for CWMP

Execute **`display`** commands in any view.

Task	Command
Display CWMP configuration.	**`display cwmp configuration`**
Display the current status of CWMP.	**`display cwmp status`**

CWMP configuration examples

Example: Configuring CWMP

Network configuration

As shown in Figure 4, use H3C IMC BIMS as the ACS to bulk-configure the devices (CPEs), and assign ACS attributes to the CPEs from the DHCP server.

The configuration files for the CPEs in equipment rooms A and B are **configure1.cfg** and **configure2.cfg**, respectively.

Figure 4 Network diagram

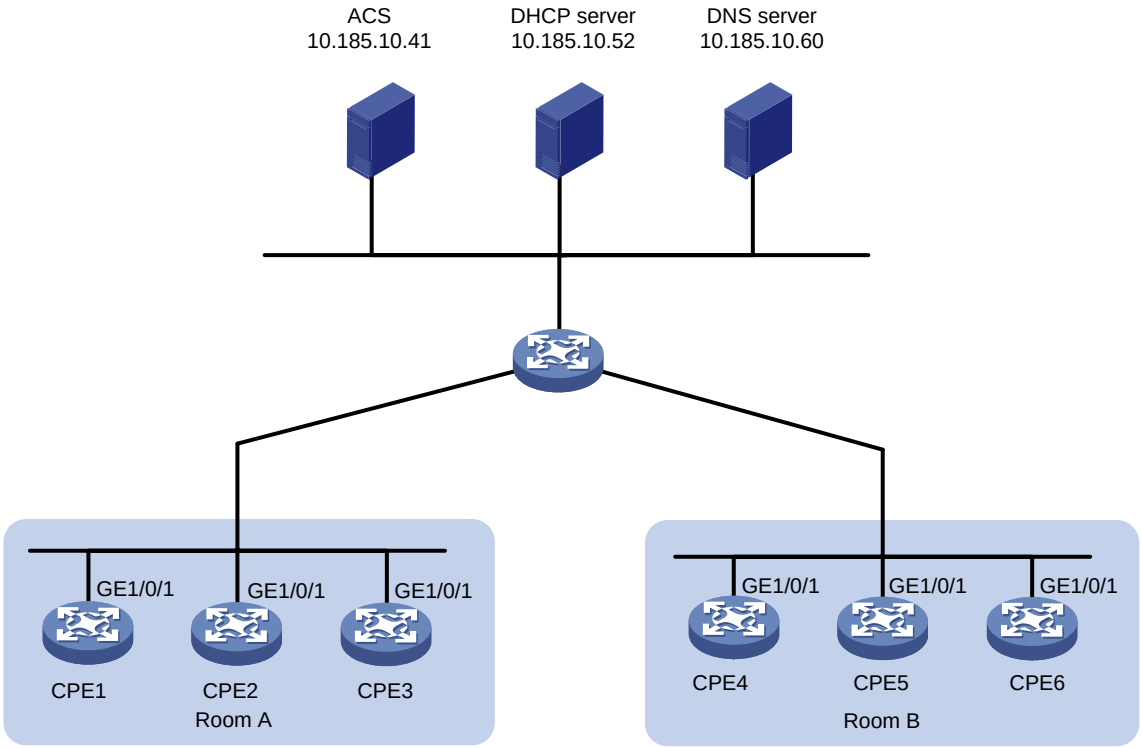


Table 4 shows the ACS attributes for the CPEs to connect to the ACS.

Table 4 ACS attributes

Item	Setting
Preferred ACS URL	http://10.185.10.41:9090
ACS username	admin
ACS password	12345

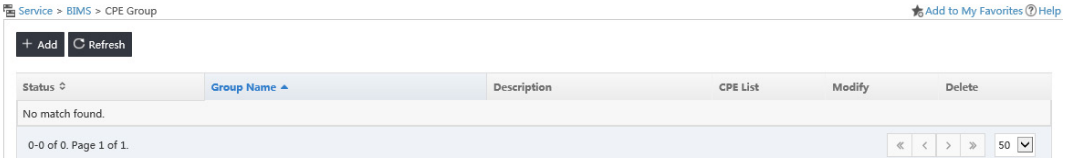
Table 5 lists serial numbers of the CPEs.

Table 5 CPE list

Room	Device	Serial number
A	CPE 1	210231A95YH10C000045
	CPE 2	210235AOLNH12000010

Room	Device	Serial number
	CPE 3	210235AOLNH12000015
B	CPE 4	210235AOLNH12000017
	CPE 5	210235AOLNH12000020
	CPE 6	210235AOLNH12000022

Configuring the ACS



Figures in this section are for illustration only.

To configure the ACS:

1. Log in to the ACS:
   a. Launch a Web browser on the ACS configuration terminal.
   b. In the address bar of the Web browser, enter the ACS URL and port number. This example uses **http://10.185.10.41:8080/imc**.
   c. On the login page, enter the ACS login username and password, and then click **Login**.
2. Create a CPE group for each equipment room:
   a. Select **Service** > **BIMS** > **CPE Group** from the top navigation bar.

      The **CPE Group** page appears.

      Figure 5 CPE Group page

   b. Click **Add**.
   c. Enter a username, and then click **OK**.

      Figure 6 Adding a CPE group

   d. Repeat the previous two steps to create a CPE group for CPEs in Room B.
3. Add CPEs to the CPE group for each equipment room:
   a. Select **Service** > **BIMS** > **Resource Management** > **Add CPE** from the top navigation bar.
   b. On the **Add CPE** page, configure the following parameters:
      - **Authentication Type**—Select **ACS UserName**.
      - **CPE Name**—Enter a CPE name.
      - **ACS Username**—Enter **admin**.
      - **ACS Password Generated**—Select **Manual Input**.
      - **ACS Password**—Enter a password for ACS authentication.

- **ACS Confirm Password**—Re-enter the password.
- **CPE Model**—Select the CPE model.
- **CPE Group**—Select the CPE group.

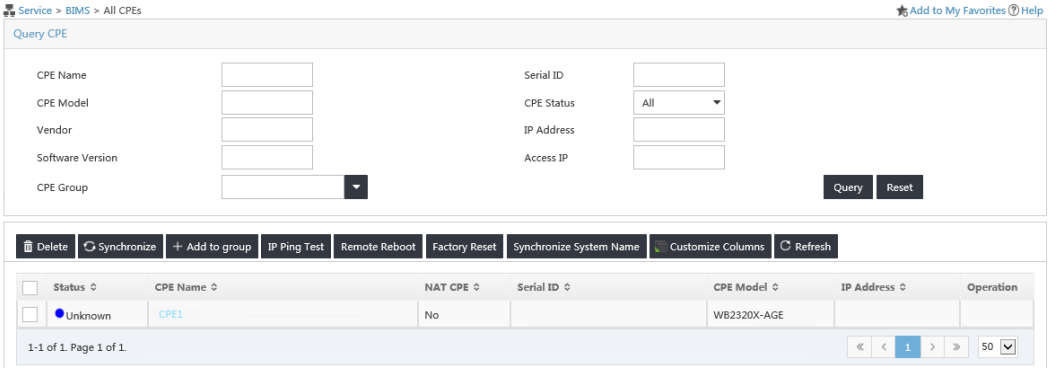


Figure 7 Adding a CPE

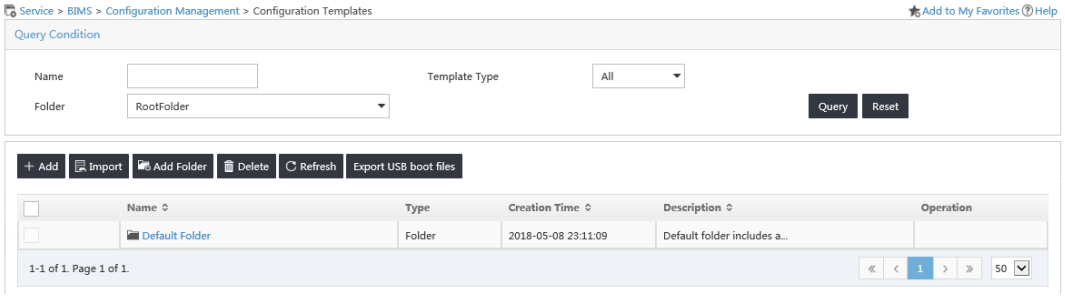
c. Click **OK**.

d. Verify that the CPE has been added successfully from the **All CPEs** page.

Figure 8 Viewing CPEs



e. Repeat the previous steps to add CPE 2 and CPE 3 to the CPE group for Room A, and add CPEs in Room B to the CPE group for Room B.

4. Configure a configuration template for each equipment room:

a. Select **Service** > **BIMS** > **Configuration Management** > **Configuration Templates** from the top navigation bar.

Figure 9 Configuration Templates page

b. Click **Import**.

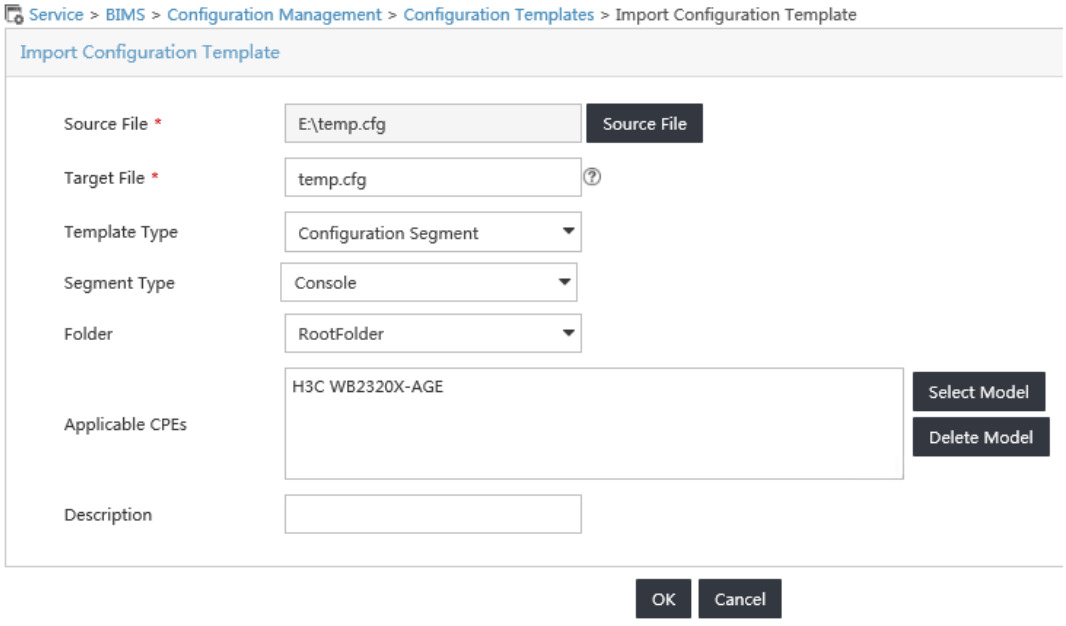
c. Select a source configuration file, select **Configuration Segment** as the template type, and then click **OK**.

The created configuration template will be displayed in the **Configuration Template** list after a successful file import.

IMPORTANT:

If the first command in the configuration template file is **`system-view`**, make sure no characters exist in front of the command.

Figure 10 Importing a configuration template



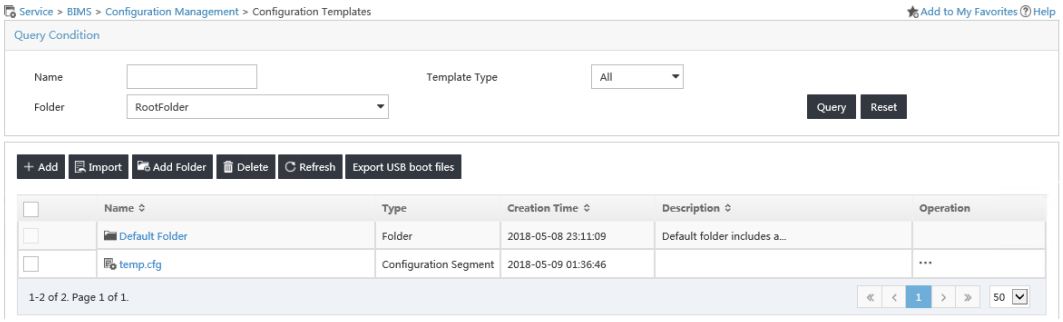


Figure 11 Configuration Template list

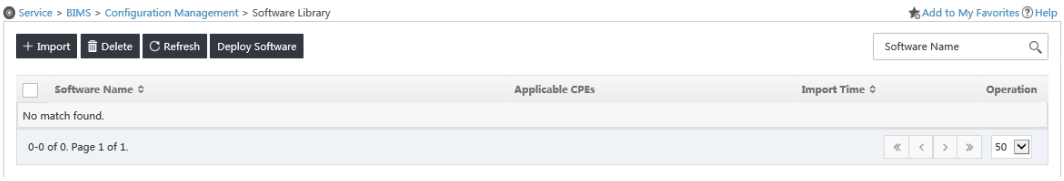

d. Repeat the previous steps to configure a configuration template for Room B.

5. Add software library entries:

a. Select **Service** > **BIMS** > **Configuration Management** > **Software Library** from the top navigation bar.

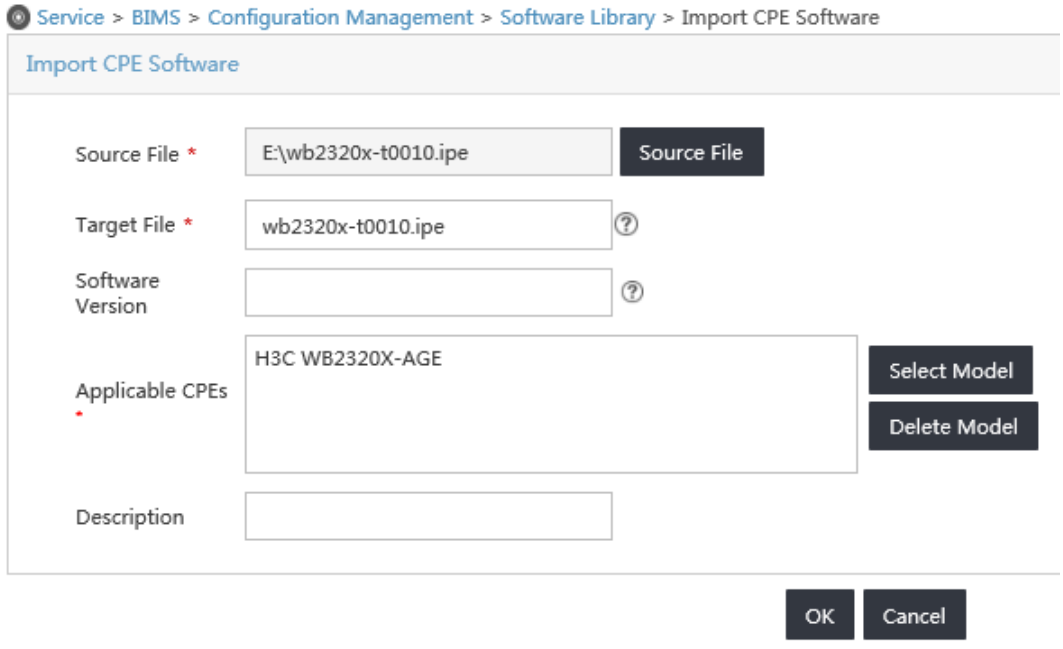

Figure 12 Software Library page

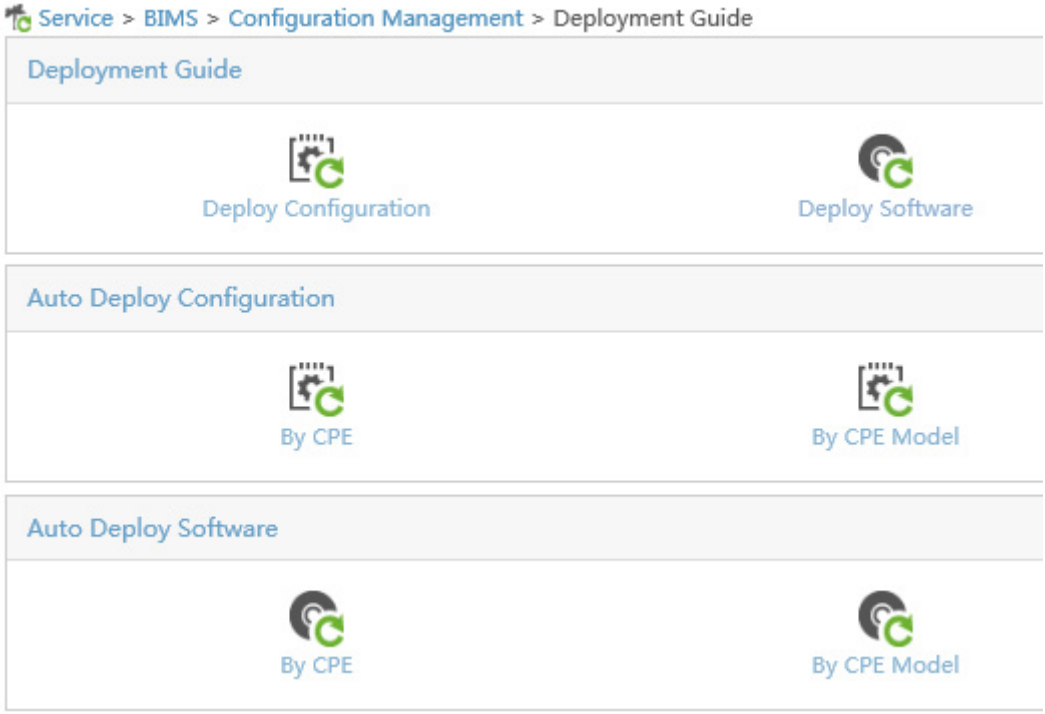
b. Click **Import**.

c. Select a source file, and then click **OK**.

Figure 13 Importing CPE software

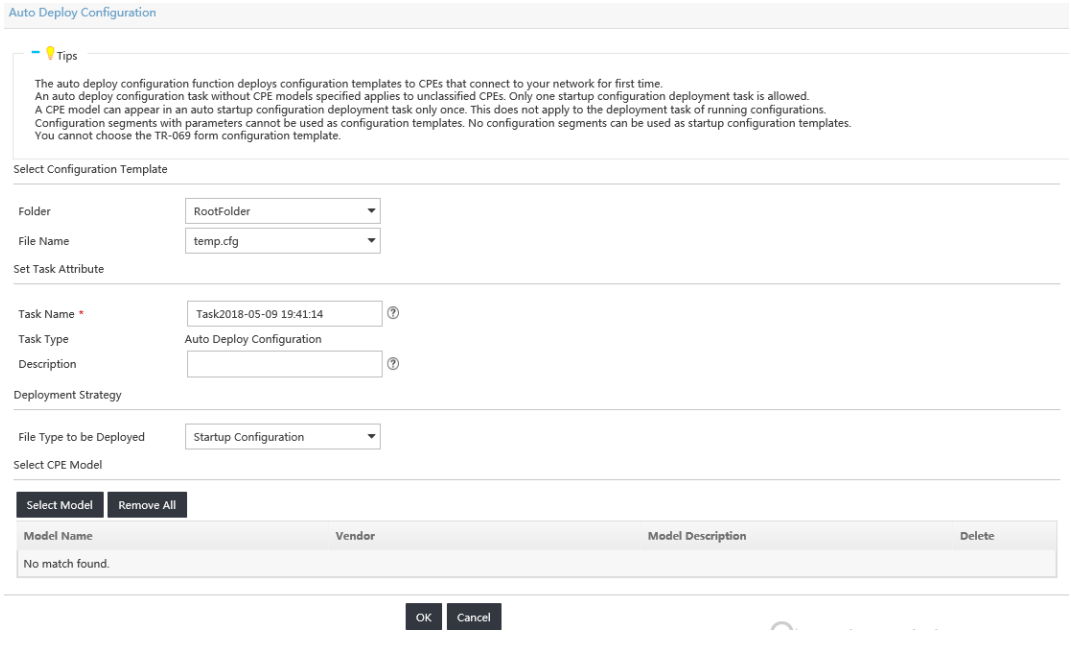


d. Repeat the previous steps to add software library entries for CPEs of different models.

6. Create an auto-deployment task for each equipment room:

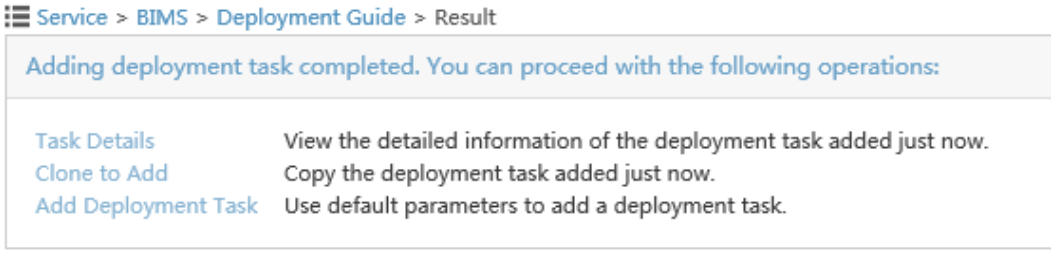
a. Select **Service** > **BIMS** > **Configuration Management** > **Deployment Guide** from the top navigation bar.

Figure 14 Deployment Guide



b. Click **By CPE Model** from the **Auto Deployment Configuration** field.

c. Select a configuration template, select **Startup Configuration** from the **File Type to be Deployed** list, and click **Select Model** to select CPEs in Room A. Then, click **OK**.



You can search for CPEs by CPE group.

Figure 15 Auto deployment configuration

d. Click **OK** on the **Auto Deploy Configuration** page.

Figure 16 Operation result

e. Repeat the previous steps to add a deployment task for CPEs in Room B.

Configuring the DHCP server

In this example, an H3C device is operating as the DHCP server.

1. Configure an IP address pool to assign IP addresses and DNS server address to the CPEs. This example uses subnet 10.185.10.0/24 for IP address assignment.

Enable DHCP.

```
<DHCP_server> system-view
[DHCP_server] dhcp enable
```

Enable DHCP server on VLAN-interface 1.

```
[DHCP_server] interface vlan-interface 1
[DHCP_server-Vlan-interface1] dhcp select server
[DHCP_server-Vlan-interface1] quit
```

Exclude the DNS server address 10.185.10.60 and the ACS IP address 10.185.10.41 from dynamic allocation.

```
[DHCP_server] dhcp server forbidden-ip 10.185.10.41
[DHCP_server] dhcp server forbidden-ip 10.185.10.60
```

Create DHCP address pool 0.

```
[DHCP_server] dhcp server ip-pool 0
```

Assign subnet 10.185.10.0/24 to the address pool, and specify the DNS server address 10.185.10.60 in the address pool.

```
[DHCP_server-dhcp-pool-0] network 10.185.10.0 mask 255.255.255.0
[DHCP_server-dhcp-pool-0] dns-list 10.185.10.60
```

2. Configure DHCP Option 43 to contain the ACS URL, username, and password in hexadecimal format.

```
[DHCP_server-dhcp-pool-0] option 43 hex
013B687474703A2F2F6163732E6461746162617365653A393039302F616373207669636B79203132333
435
```

Configuring the DNS server

Map http://acs.database:9090 to http://10.185.1.41:9090 on the DNS server. For more information about DNS configuration, see DNS server documentation.

Connecting the CPEs to the network

Connect CPE 1 to the network, and then power on the CPE. (Details not shown.)

Log in to CPE 1 and configure its VLAN-interface 2 to use DHCP for IP address acquisition and assign interface GigabitEthernet 1/0/1 to VLAN 2.

```
<CPE1> system-view
[CPE1] vlan 2
[CPE1-vlan2] quit
```

```
[CPE1] interface gigabitethernet 1/0/1
[CPE1-GigabitEthernet1/0/1] port access vlan 2
[CPE1-GigabitEthernet1/0/1] quit
[CPE1] interface vlan-interface 2
[CPE1-Vlan-interface2] ip address dhcp-alloc
```

Repeat the previous steps to configure the other CPEs.

Verifying the configuration

Execute the **display current-configuration** command to verify that the running configurations on CPEs are the same as the configurations issued by the ACS.

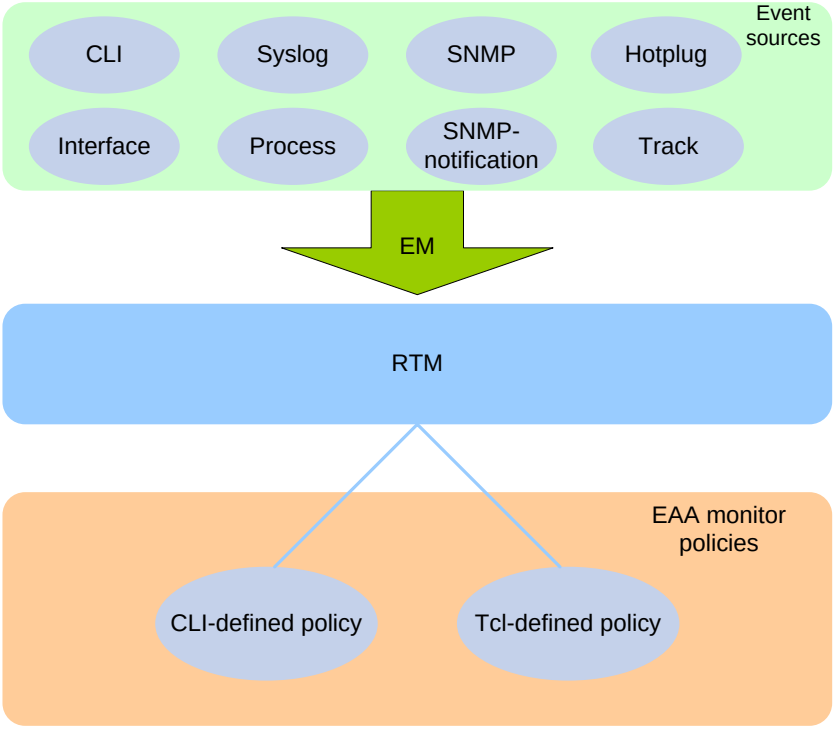
Configuring EAA



About EAA

Embedded Automation Architecture (EAA) is a monitoring framework that enables you to self-define monitored events and actions to take in response to an event. It allows you to create monitor policies by using the CLI or Tcl scripts.

EAA framework

EAA framework includes a set of event sources, a set of event monitors, a real-time event manager (RTM), and a set of user-defined monitor policies, as shown in Figure 1.

Figure 1 EAA framework

Event sources

Event sources are software or hardware modules that trigger events (see Figure 1).

For example, the CLI module triggers an event when you enter a command. The Syslog module (the information center) triggers an event when it receives a log message.

Event monitors

EAA creates one event monitor to monitor the system for the event specified in each monitor policy. An event monitor notifies the RTM to run the monitor policy when the monitored event occurs.

RTM

RTM manages the creation, state machine, and execution of monitor policies.

EAA monitor policies

A monitor policy specifies the event to monitor and actions to take when the event occurs.

You can configure EAA monitor policies by using the CLI or Tcl.

A monitor policy contains the following elements:

- One event.
- A minimum of one action.
- A minimum of one user role.
- One running time setting.

For more information about these elements, see "Elements in a monitor policy."

Elements in a monitor policy

Elements in an EAA monitor policy include event, action, user role, and runtime.

Event

Table 1 shows types of events that EAA can monitor.

Table 1 Monitored events

Event type	Description
CLI	CLI event occurs in response to monitored operations performed at the CLI. For example, a command is entered, a question mark (?) is entered, or the **Tab** key is pressed to complete a command.
Hotplug	Hot-swapping event occurs when the monitored member device joins or leaves the IRF fabric.
Interface	Each interface event is associated with two user-defined thresholds: start and restart. An interface event occurs when the monitored interface traffic statistic crosses the start threshold in the following situations: • The statistic crosses the start threshold for the first time. • The statistic crosses the start threshold each time after it crosses the restart threshold.
process	Process event occurs in response to a state change of the monitored process (such as an exception, shutdown, start, or restart). Both manual and automatic state changes can cause the event to occur.
SNMP	Each SNMP event is associated with two user-defined thresholds: start and restart. SNMP event occurs when the monitored MIB variable's value crosses the start threshold in the following situations: • The monitored variable's value crosses the start threshold for the first time. • The monitored variable's value crosses the start threshold each time after it crosses the restart threshold.
SNMP-Notification	SNMP-Notification event occurs when the monitored MIB variable's value in an SNMP notification matches the specified condition. For example, the broadcast traffic rate on an Ethernet interface reaches or exceeds 30%.
Syslog	Syslog event occurs when the information center receives the monitored log within a specific period. NOTE: The log that is generated by the EAA RTM does not trigger the monitor policy to run.
Track	Track event occurs when the state of the track entry changes from Positive to Negative or from Negative to Positive. If you specify multiple track entries for a policy, EAA triggers the policy only when the state of all the track entries changes from Positive

Event type	Description
	(Negative) to Negative (Positive). If you set a suppress time for a policy, the timer starts when the policy is triggered. The system does not process the messages that report the track entry state change from Positive (Negative) to Negative (Positive) until the timer times out.

Action

You can create a series of order-dependent actions to take in response to the event specified in the monitor policy.

The following are available actions:

- Executing a command.
- Executing a reboot without saving the running configuration.
- Enabling an active/standby switchover.
- Sending a log.

User role

For EAA to execute an action in a monitor policy, you must assign the policy the user role that has access to the action-specific commands and resources. If EAA lacks access to an action-specific command or resource, EAA does not perform the action and all the subsequent actions.

For example, a monitor policy has four actions numbered from 1 to 4. The policy has user roles that are required for performing actions 1, 3, and 4. However, it does not have the user role required for performing action 2. When the policy is triggered, EAA executes only action 1.

For more information about user roles, see RBAC in *Fundamentals Configuration Guide*.

Runtime

The runtime limits the amount of time that the monitor policy runs its actions from the time it is triggered. This setting prevents a policy from running its actions permanently to occupy resources.

EAA environment variables

EAA environment variables decouple the configuration of action arguments from the monitor policy so you can modify a policy easily.

An EAA environment variable is defined as a <*variable_name variable_value*> pair and can be used in different policies. When you define an action, you can enter a variable name with a leading dollar sign (**$***variable_name*). EAA will replace the variable name with the variable value when it performs the action.

To change the value for an action argument, modify the value specified in the variable pair instead of editing each affected monitor policy.

EAA environment variables include system-defined variables and user-defined variables.

System-defined variables

System-defined variables are provided by default, and they cannot be created, deleted, or modified by users. System-defined variable names start with an underscore (_) sign. The variable values are set automatically depending on the event setting in the policy that uses the variables.

System-defined variables include the following types:

- **Public variable**—Available for any events.
- **Event-specific variable**—Available only for the specific event type. For example, the CLI event-specific variable is _cmd. When an CLI event is triggered, the value of _cmd is the command line matching the monitor policy.

Table 2 shows all system-defined variables.

Table 2 System-defined EAA environment variables by event type

Event	Variable name and description
Any event	_event_id: Event ID. _event_type: Event type. _event_type_string: Event type description. _event_time: Time when the event occurs. _event_severity: Severity level of an event.
CLI	_cmd: Commands that are matched.
Hotplug	_slot: ID of the member device that joins or leaves the IRF fabric
Interface	_ifname: Interface name.
Process	_process_name: Process name.
SNMP	_oid: OID of the MIB variable where an SNMP operation is performed. _oid_value: Value of the MIB variable.
SNMP-Notification	_oid: OID that is included in the SNMP notification.
Syslog	_syslog_pattern: Log message content.

User-defined variables

You can use user-defined variables for all types of events.

User-defined variable names can contain digits, characters, and the underscore sign (_), except that the underscore sign cannot be the leading character.

Restrictions and guidelines

Make sure the actions in different policies do not conflict. Policy execution result will be unpredictable if policies that conflict in actions are running concurrently.

You can assign the same policy name to a CLI-defined policy and a Tcl-defined policy. However, you cannot assign the same name to policies that are the same type.

A monitor policy supports only one event and runtime. If you configure multiple events for a policy, the most recent one takes effect.

A monitor policy supports a maximum of 64 valid user roles. User roles added after this limit is reached do not take effect.

Configuring a user-defined EAA environment variable

About this task

Configure user-defined EAA environment variables so that you can use them when creating EAA monitor policies.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Configure a user-defined EAA environment variable.

rtm environment *var-name var-value*

For the system-defined variables, see Table 2.

Configuring a monitor policy from the CLI

Tasks at a glance

1. Creating a CLI-defined policy
2. (Optional.) Setting the size for the EAA-monitored log buffer
3. Configuring an event
4. Configuring an action
5. Assigning a user role to a CLI-defined policy
6. Configuring the policy action runtime
7. Enabling the CLI-defined monitor policy

Creating a CLI-defined policy

1. Enter system view.

   system-view
2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

Setting the size for the EAA-monitored log buffer

About this task

This task is required only when a syslog event is specified for a CLI-defined policy.

After you specify and enable a syslog event EAA monitor policy, the system copies a log to the EAA-monitored log buffer upon generation of the log. The EAA module compares the log in the buffer with the log event. If they match, the monitor policy is triggered.

Under normal circumstances, you can use the default size setting for the EAA-monitored log buffer. However, when a feature is abnormal or multiple debugging functions are enabled, a large number of logs might be generated in a short time, causing some logs to be discarded before they are matched. In this case, you can increase the size of the EAA-monitored log buffer according to the device memory usage.

Procedure

1. Enter system view.

   system-view
2. Set the size for the EAA-monitored log buffer.

   rtm event syslog buffer-size *buffer-size*

   By default, the EAA-monitored log buffer can store a maximum of 50000 logs.

Configuring an event

Restrictions and guidelines

A monitor policy supports only one event. If you configure multiple events for a policy, the most recent one takes effect.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

3. Configure an event for the policy. Choose one option as needed:

   - Configure a CLI event.

     event cli { **async** [**skip**] | **sync** } **mode** { **execute** | **help** | **tab** } **pattern** *regular-exp*

   - Configure a hotplug event.

     event hotplug [**insert** | **remove**] **slot** *slot-number*

   - Configure an interface event.

     event interface *interface-list* **monitor-obj** *monitor-obj* **start-op** *start-op* **start-val** *start-val* **restart-op** *restart-op* **restart-val** *restart-val* [**interval** *interval*]

   - Configure a process event.

     event process { **exception** | **restart** | **shutdown** | **start** } [**name** *process-name* [**instance** *instance-id*]] [**slot** *slot-number*]

   - Configure an SNMP event.

     event snmp oid *oid* **monitor-obj** { **get** | **next** } **start-op** *start-op* **start-val** *start-val* **restart-op** *restart-op* **restart-val** *restart-val* [**interval** *interval*]

   - Configure an SNMP-Notification event.

     event snmp-notification oid *oid* **oid-val** *oid-val* **op** *op* [**drop**]

   - Configure a Syslog event.

     event syslog priority { *priority* | **all** } **msg** *msg* **occurs** *times* **period** *period*

   - Configure a track event.

     event track *track-list* **state { negative** | **positive** } [**suppress-time** *suppress-time*]

   By default, a monitor policy does not contain an event.

Configuring an action

Restrictions and guidelines

You can configure a series of actions to be executed in response to the event specified in a monitor policy. EAA executes the actions in ascending order of action IDs. When you add actions to a policy, you must make sure the execution order is correct. If two actions have the same ID, the most recent one takes effect.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

3. Configure the actions to take when the event occurs. Choose the options to configure as needed:

- Configure a CLI action.
  action *number* **cli** *command-line*
- Configure a reboot action.
  action *number* **reboot** [**slot** *slot-number*]
- Configure an active/standby switchover action.
  action *number* **switchover**
- Configure a logging action.
  action *number* **syslog priority** *priority* **facility** *local-number* **msg** *msg-body*

By default, a monitor policy does not contain any actions.

Assigning a user role to a CLI-defined policy

Restrictions and guidelines

An EAA policy cannot have both the **security-audit** user role and any other user roles. Any previously assigned user roles are automatically removed when you assign the **security-audit** user role to the policy. The previously assigned **security-audit** user role is automatically removed when you assign any other user roles to the policy.

Procedure

1. Enter system view.
   system-view
2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*
3. (Optional.) Assign a user role to the policy.
   user-role *role-name*
   By default, a monitor policy contains user roles that its creator had at the time of policy creation.

Configuring the policy action runtime

1. Enter system view.
   system-view
2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*
3. (Optional.) Configure the policy action runtime.
   running-time *time*
   The default policy action runtime is 20 seconds.
   If you configure multiple action runtimes for a policy, the most recent one takes effect.

Enabling the CLI-defined monitor policy

About this task

A CLI-defined monitor policy takes effect only after you enable it.

Procedure

1. Enter system view.
   system-view

2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

3. Enable the CLI-defined policy.

   commit

Configuring a monitor policy by using Tcl

About this task

A Tcl script contains two parts: Line 1 and the other lines.

- Line 1

  Line 1 defines the event, user roles, and policy action runtime. After you create and enable a Tcl monitor policy, the device immediately parses, delivers, and executes Line 1.

  Line 1 must use the following format:

  ::platformtools::rtm::event_register *event-type arg1 arg2 arg3* … **user-role** *role-name1* | [**user-role** *role-name2* | […]] [**running-time** *running-time*]

  - The *arg1 arg2 arg3* … arguments represent event matching rules. If an argument value contains spaces, use double quotation marks ("") to enclose the value. For example, "a b c."
  - The configuration requirements for the *event-type*, *user-role*, and *running-time* arguments are the same as those for a CLI-defined monitor policy.

- The other lines

  From the second line, the Tcl script defines the actions to be executed when the monitor policy is triggered. You can use multiple lines to define multiple actions. The system executes these actions in sequence. The following actions are available:

  - Standard Tcl commands.
  - EAA-specific Tcl actions:
    - switchover (**::platformtools::rtm::action switchover**)
    - syslog (**::platformtools::rtm::action syslog priority** *priority* **facility** *local-number* **msg** *msg-body*). For more information about these arguments, see EAA commands in *Network Management and Monitoring Command Reference*.
  - Commands supported by the device.

Restrictions and guidelines

To revise the Tcl script of a policy, you must suspend all monitor policies first, and then resume the policies after you finish revising the script. The system cannot execute a Tcl-defined policy if you edit its Tcl script without first suspending these policies.

Procedure

1. Download the Tcl script file to the device by using FTP or TFTP.

   For more information about using FTP and TFTP, see *Fundamentals Configuration Guide*.

2. Create and enable a Tcl monitor policy.

   a. Enter system view.

      system-view

   b. Create a Tcl-defined policy and bind it to the Tcl script file.

      rtm tcl-policy *policy-name tcl-filename*

   By default, no Tcl policies exist.

Make sure the script file is saved on all IRF member devices. This practice ensures that the policy can run correctly after a master/subordinate switchover occurs or the member device where the script file resides leaves the IRF.

Suspending monitor policies

About this task

This task suspends all CLI-defined and Tcl-defined monitor policies. If a policy is running when you perform this task, the system suspends the policy after it executes all the actions.

Restrictions and guidelines

To restore the operation of the suspended policies, execute the **undo rtm scheduler suspend** command.

Procedure

1. Enter system view.
   system-view
2. Suspend monitor policies.
   rtm scheduler suspend

Display and maintenance commands for EAA

Execute **display** commands except for the **display this** command in any view.

Task	Command
Display the running configuration of all CLI-defined monitor policies.	**display current-configuration**
Display user-defined EAA environment variables.	**display rtm environment** [*var-name*]
Display EAA monitor policies.	**display rtm policy** { **active** | **registered** [**verbose**] } [*policy-name*]
Display the running configuration of a CLI-defined monitor policy in CLI-defined monitor policy view.	**display this**

EAA configuration examples

Example: Configuring a CLI event monitor policy by using Tcl

Network configuration

As shown in Figure 2, use Tcl to create a monitor policy on the Device. This policy must meet the following requirements:

- EAA sends the log message "rtm_tcl_test is running" when a command that contains the **display this** string is entered.
- The system executes the command only after it executes the policy successfully.

Figure 2 Network diagram

Procedure

Edit a Tcl script file (rtm_tcl_test.tcl, in this example) for EAA to send the message "rtm_tcl_test is running" when a command that contains the **display this** string is executed.

```
::platformtools::rtm::event_register cli sync mode execute pattern display this
user-role network-admin
::platformtools::rtm::action syslog priority 1 facility local4 msg rtm_tcl_test is
running
```

Download the Tcl script file from the TFTP server at **1.2.1.1**.

```
<Sysname> tftp 1.2.1.1 get rtm_tcl_test.tcl
```

Create Tcl-defined policy **test** and bind it to the Tcl script file.

```
<Sysname> system-view
[Sysname] rtm tcl-policy test rtm_tcl_test.tcl
[Sysname] quit
```

Verifying the configuration

Execute the **display rtm policy registered** command to verify that a Tcl-defined policy named **test** is displayed in the command output.

```
<Sysname> display rtm policy registered
Total number: 1
Type  Event             TimeRegistered       PolicyName
TCL   CLI               Aug 01 09:47:12 2019 test
```

Enable the information center to output log messages to the current monitoring terminal.

```
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
[Sysname] quit
```

Execute the **display this** command. Verify that the system displays an "rtm_tcl_test is running" message and a message that the policy is being executed successfully.

```
[Sysname] display this
%Aug  1 09:50:04:634 2019 Sysname RTM/1/RTM_ACTION: rtm_tcl_test is running
%Aug  1 09:50:04:636 2019 Sysname RTM/6/RTM_POLICY: TCL policy test is running
successfully.
#
return
```

Example: Configuring a CLI event monitor policy from the CLI

Network configuration

Configure a policy from the CLI to monitor the event that occurs when a question mark (?) is entered at the command line that contains letters and digits.

When the event occurs, the system executes the command and sends the log message "hello world" to the information center.

Procedure

Create CLI-defined policy **test** and enter its view.

```
<Sysname> system-view
[Sysname] rtm cli-policy test
```

Add a CLI event that occurs when a question mark (?) is entered at any command line that contains letters and digits.

```
[Sysname-rtm-test] event cli async mode help pattern [a-zA-Z0-9]
```

Add an action that sends the message "hello world" with a priority of 4 from the logging facility **local3** when the event occurs.

```
[Sysname-rtm-test] action 0 syslog priority 4 facility local3 msg "hello world"
```

Add an action that enters system view when the event occurs.

```
[Sysname-rtm-test] action 2 cli system-view
```

Add an action that creates VLAN 2 when the event occurs.

```
[Sysname-rtm-test] action 3 cli vlan 2
```

Set the policy action runtime to 2000 seconds.

```
[Sysname-rtm-test] running-time 2000
```

Specify the **network-admin** user role for executing the policy.

```
[Sysname-rtm-test] user-role network-admin
```

Enable the policy.

```
[Sysname-rtm-test] commit
```

Verifying the configuration

Execute the **display rtm policy registered** command to verify that a CLI-defined policy named **test** is displayed in the command output.

```
[Sysname-rtm-test] display rtm policy registered
Total number: 1
Type  Event      TimeRegistered       PolicyName
CLI   CLI        Aug  1 14:56:50 2019 test
```

Enable the information center to output log messages to the current monitoring terminal.

```
[Sysname-rtm-test] return
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
[Sysname] quit
```

Enter a question mark (?) at a command line that contains a letter **d**. Verify that the system displays a "hello world" message and a message that the policy is being executed successfully on the terminal screen.

```
<Sysname> d?
  debugging
  delete
  diagnostic-logfile
  dir
  display
```

```
<Sysname>d%Aug  1 14:57:20:218 2019 Sysname RTM/4/RTM_ACTION: "hello world"
%Aug  1 14:58:11:170 2019 Sysname RTM/6/RTM_POLICY: CLI policy test is running
successfully.
```

Example: Configuring a CLI event monitor policy with EAA environment variables from the CLI

Network configuration

Define an environment variable to match the IP address 1.1.1.1.

Configure a policy from the CLI to monitor the event that occurs when a command line that contains **loopback0** is executed. In the policy, use the environment variable for IP address assignment.

When the event occurs, the system performs the following tasks:

- Creates the Loopback 0 interface.
- Assigns 1.1.1.1/24 to the interface.
- Sends the matching command line to the information center.

Procedure

Configure an EAA environment variable for IP address assignment. The variable name is **loopback0IP**, and the variable value is **1.1.1.1**.

```
<Sysname> system-view
[Sysname] rtm environment loopback0IP 1.1.1.1
```

Create the CLI-defined policy **test** and enter its view.

```
[Sysname] rtm cli-policy test
```

Add a CLI event that occurs when a command line that contains **loopback0** is executed.

```
[Sysname-rtm-test] event cli async mode execute pattern loopback0
```

Add an action that enters system view when the event occurs.

```
[Sysname-rtm-test] action 0 cli system-view
```

Add an action that creates the interface Loopback 0 and enters loopback interface view.

```
[Sysname-rtm-test] action 1 cli interface loopback 0
```

Add an action that assigns the IP address 1.1.1.1 to Loopback 0. The **loopback0IP** variable is used in the action for IP address assignment.

```
[Sysname-rtm-test] action 2 cli ip address $loopback0IP 24
```

Add an action that sends the matching **loopback0** command with a priority of 0 from the logging facility **local7** when the event occurs.

```
[Sysname-rtm-test] action 3 syslog priority 0 facility local7 msg $_cmd
```

Specify the **network-admin** user role for executing the policy.

```
[Sysname-rtm-test] user-role network-admin
```

Enable the policy.

```
[Sysname-rtm-test] commit
[Sysname-rtm-test] return
<Sysname>
```

Verifying the configuration

Enable the information center to output log messages to the current monitoring terminal.

```
<Sysname> terminal monitor
```

```
The current terminal is enabled to display logs.
<Sysname> terminal log level debugging
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
```

Execute the **loopback0** command. Verify that the system displays a "loopback0" message and a message that the policy is being executed successfully on the terminal screen.

```
[Sysname] interface loopback0
[Sysname-LoopBack0]%Aug  1 09:46:10:592 2019 Sysname RTM/7/RTM_ACTION: interface
loopback0
%Aug  1 09:46:10:613 2019 Sysname RTM/6/RTM_POLICY: CLI policy test is running
successfully.
```

Verify that Loopback 0 has been created and its IP address is 1.1.1.1.

```
<Sysname-LoopBack0> display interface loopback brief
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP         Description
Loop0                UP   UP(s)    1.1.1.1

<Sysname-LoopBack0>
```

Monitoring and maintaining processes

About monitoring and maintaining processes

The system software of the device is a full-featured, modular, and scalable network operating system based on the Linux kernel. The system software features run the following types of independent processes:

- **User process**—Runs in user space. Most system software features run user processes. Each process runs in an independent space so the failure of a process does not affect other processes. The system automatically monitors user processes. The system supports preemptive multithreading. A process can run multiple threads to support multiple activities. Whether a process supports multithreading depends on the software implementation.
- **Kernel thread**—Runs in kernel space. A kernel thread executes kernel code. It has a higher security level than a user process. If a kernel thread fails, the system breaks down. You can monitor the running status of kernel threads.

Process monitoring and maintenance tasks at a glance

To monitor and maintain processes, perform the following tasks:

- Monitoring and maintaining user processes
  - Monitoring and maintaining processes

    The commands in this section apply to both user processes and kernel threads.
  - Monitoring and maintaining user processes

    The commands in this section apply only to user processes.
- Monitoring and maintaining kernel threads
  - Monitoring and maintaining processes

    The commands in this section apply to both user processes and kernel threads.
  - Monitoring and maintaining kernel threads

    The commands in this section apply only to kernel threads.

Monitoring and maintaining processes

About this task

The commands in this section apply to both user processes and kernel threads. You can use the commands for the following purposes:

- Display the overall memory usage.
- Display the running processes and their memory and CPU usage.
- Locate abnormal processes.

If a process consumes excessive memory or CPU resources, the system identifies the process as an abnormal process.

- If an abnormal process is a user process, troubleshoot the process as described in "Monitoring and maintaining user processes."

- If an abnormal process is a kernel thread, troubleshoot the process as described in "Monitoring and maintaining kernel threads."

Procedure

Execute the following commands in any view.

Task	Command
Display memory usage.	**display memory** [**summary**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display process state information.	**display process** [**all** | **job** *job-id* | **name** *process-name*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display CPU usage for all processes.	**display process cpu** [**slot** *slot-number* [**cpu** *cpu-number*]]
Monitor process running state.	**monitor process** [**dumbtty**] [**iteration** *number*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Monitor thread running state.	**monitor thread** [**dumbtty**] [**iteration** *number*] [**slot** *slot-number* [**cpu** *cpu-number*]]

For more information about the **display memory** command, see *Fundamentals Command Reference*.

Monitoring and maintaining user processes

About monitoring and maintaining user processes

Use this feature to monitor abnormal user processes and locate problems.

Configuring core dump

About this task

The core dump feature enables the system to generate a core dump file each time a process crashes until the maximum number of core dump files is reached. A core dump file stores information about the process. You can send the core dump files to H3C Support to troubleshoot the problems.

Restrictions and guidelines

Core dump files consume storage resources. Enable core dump only for processes that might have problems.

Procedure

Execute the following commands in user view:

1. (Optional.) Specify the directory for saving core dump files.

   exception filepath *directory*

   By default, the directory for saving core dump files is the root directory of the default file system. For more information about the default file system, see file system management in *Fundamentals Configuration Guide*.

2. Enable core dump for a process and specify the maximum number of core dump files, or disable core dump for a process.

   process core { **maxcore** *value* | **off** } { **job** *job-id* | **name** *process-name* }

By default, a process generates a core dump file for the first exception and does not generate any core dump files for subsequent exceptions.

Display and maintenance commands for user processes

Execute **display** commands in any view and other commands in user view.

Task	Command
Display context information for process exceptions.	**display exception context** [**count** *value*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the core dump file directory.	**display exception filepath** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display log information for all user processes.	**display process log** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory usage for all user processes.	**display process memory** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display heap memory usage for a user process.	**display process memory heap job** *job-id* [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory content starting from a specified memory block for a user process.	**display process memory heap job** *job-id* **address** *starting-address* **length** *memory-length* [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the addresses of memory blocks with a specified size used by a user process.	**display process memory heap job** *job-id* **size** *memory-size* [**offset** *offset-size*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear context information for process exceptions.	**reset exception context** [**slot** *slot-number* [**cpu** *cpu-number*]]

Monitoring and maintaining kernel threads

Configuring kernel thread deadloop detection

About this task

Kernel threads share resources. If a kernel thread monopolizes the CPU, other threads cannot run, resulting in a deadloop.

This feature enables the device to detect deadloops. If a thread occupies the CPU for a specific interval, the device determines that a deadloop has occurred and generates a deadloop message.

Restrictions and guidelines

CAUTION:

Change kernel thread deadloop detection settings only under the guidance of H3C Support. Inappropriate configuration can cause system breakdown.

Procedure

1. Enter system view.

   system-view

2. Enable kernel thread deadloop detection.

   monitor kernel deadloop enable [**slot** *slot-number* [**cpu** *cpu-number* [**core** *core-number*&<1-64>]]]

   By default, kernel thread deadloop detection is enabled.

3. (Optional.) Set the threshold for identifying a kernel thread deadloop.

   monitor kernel deadloop time *time* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the threshold for identifying a kernel thread deadloop is 20 seconds.

4. (Optional.) Exclude a kernel thread from kernel thread deadloop detection.

   monitor kernel deadloop exclude-thread *tid* [**slot** *slot-number* [**cpu** *cpu-number*]]

   When enabled, kernel thread deadloop detection monitors all kernel threads by default.

5. (Optional.) Specify the action to be taken in response to a kernel thread deadloop.

   monitor kernel deadloop action { **reboot** | **record-only** } [**slot** *slot-number* [**cpu** *cpu-number*]]

   The default action is **reboot**.

Configuring kernel thread starvation detection

About this task

Starvation occurs when a thread is unable to access shared resources.

Kernel thread starvation detection enables the system to detect and report thread starvation. If a thread is not executed within a specific interval, the system determines that a starvation has occurred and generates a starvation message.

Thread starvation does not impact system operation. A starved thread can automatically run when certain conditions are met.

Restrictions and guidelines

CAUTION:

Configure kernel thread starvation detection only under the guidance of H3C Support. Inappropriate configuration can cause system breakdown.

Procedure

1. Enter system view.

   system-view

2. Enable kernel thread starvation detection.

   monitor kernel starvation enable [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, kernel thread starvation detection is disabled.

3. (Optional.) Set the threshold for identifying a kernel thread starvation.

   monitor kernel starvation time *time* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the threshold for identifying a kernel thread starvation is 120 seconds.

4. (Optional.) Exclude a kernel thread from kernel thread starvation detection.

monitor kernel starvation exclude-thread *tid* [**slot** *slot-number* [**cpu** *cpu-number*]]

When enabled, kernel thread starvation detection monitors all kernel threads by default.

Display and maintenance commands for kernel threads

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display kernel thread deadloop detection configuration.	**display kernel deadloop configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread deadloop information.	**display kernel deadloop** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread exception information.	**display kernel exception** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread reboot information.	**display kernel reboot** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread starvation detection configuration.	**display kernel starvation configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]

Configuring port mirroring

About port mirroring

Port mirroring copies the packets passing through a port to a port that connects to a data monitoring device for packet analysis.

Terminology

The following terms are used in port mirroring configuration.

Mirroring source

The mirroring sources can be one or more monitored ports called source ports.

Packets passing through mirroring sources are copied to a port connecting to a data monitoring device for packet analysis. The copies are called mirrored packets.

Source device

The device where the mirroring sources reside is called a source device.

Mirroring destination

The mirroring destination connects to a data monitoring device and is the destination port (also known as the monitor port) of mirrored packets. Mirrored packets are sent out of the monitor port to the data monitoring device.

A monitor port might receive multiple copies of a packet when it monitors multiple mirroring sources. For example, two copies of a packet are received on Port A when the following conditions exist:

- Port A is monitoring bidirectional traffic of Port B and Port C on the same device.
- The packet travels from Port B to Port C.

Destination device

The device where the monitor port resides is called the destination device.

Mirroring direction

The mirroring direction specifies the direction of the traffic that is copied on a mirroring source.

- **Inbound**—Copies packets received.
- **Outbound**—Copies packets sent.
- **Bidirectional**—Copies packets received and sent.

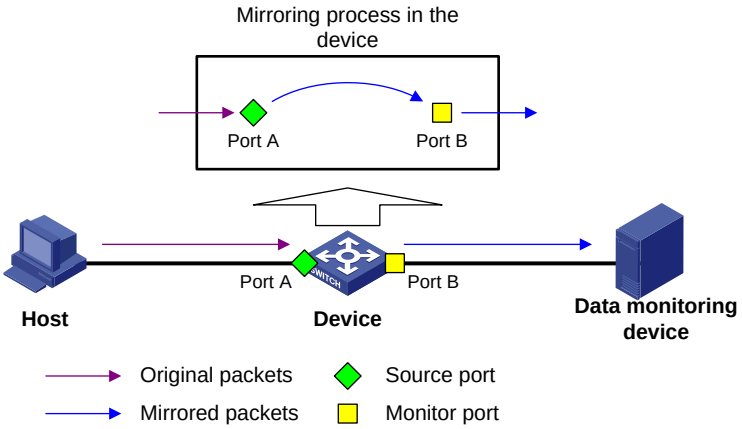
Mirroring group

Port mirroring is implemented through mirroring groups. Mirroring groups can be classified into local mirroring groups, remote source groups, and remote destination groups.

Reflector port, egress port, and remote probe VLAN

Reflector ports, remote probe VLANs, and egress ports are used for Layer 2 remote port mirroring. The remote probe VLAN is a dedicated VLAN for transmitting mirrored packets to the destination device. Both the reflector port and egress port reside on a source device and send mirrored packets to the remote probe VLAN.

On port mirroring devices, all ports except source, destination, reflector, and egress ports are called common ports.



Port mirroring classification

Port mirroring can be classified into local port mirroring and remote port mirroring.

- **Local port mirroring**—The source device is directly connected to a data monitoring device. The source device also acts as the destination device and forwards mirrored packets directly to the data monitoring device.
- **Remote port mirroring**—The source device is not directly connected to a data monitoring device. The source device sends mirrored packets to the destination device, which forwards the packets to the data monitoring device. Because the source device and destination device are on the same Layer 2 network, remote port mirroring is also called Layer 2 remote port mirroring or remote SPAN (RSPAN).

Local port mirroring

Figure 1 Local port mirroring implementation

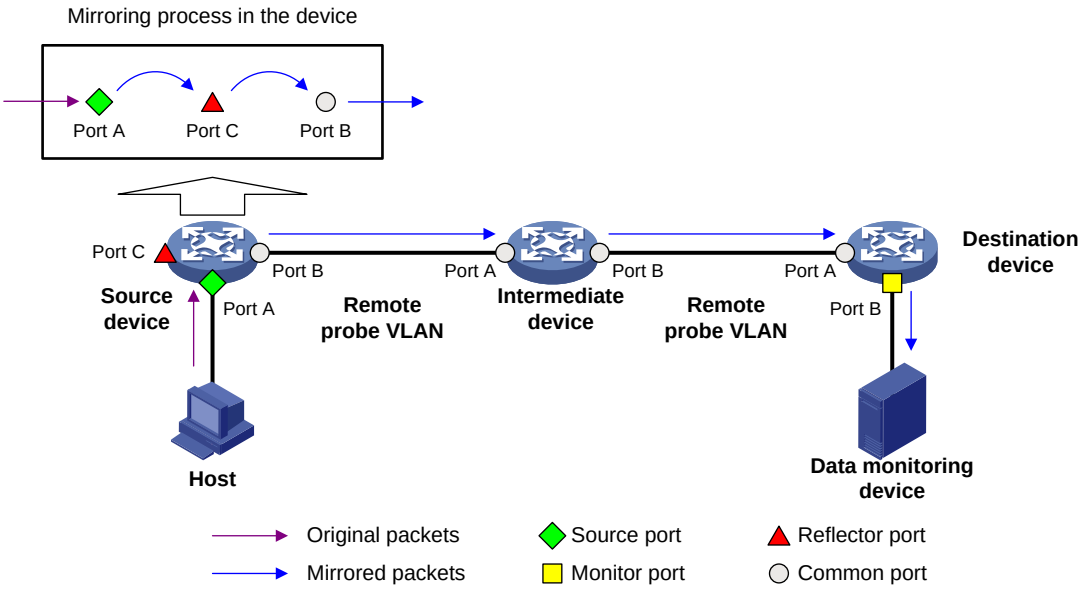
As shown in Figure 1, the source port (Port A) and the monitor port (Port B) reside on the same device. Packets received on Port A are copied to Port B. Port B then forwards the packets to the data monitoring device for analysis.

Layer 2 remote port mirroring

In Layer 2 remote port mirroring, the mirroring sources and destination reside on different devices and are in different mirroring groups.

A remote source group is a mirroring group that contains the mirroring sources. A remote destination group is a mirroring group that contains the mirroring destination. Intermediate devices are the devices between the source device and the destination device.

Layer 2 remote port mirroring can be implemented through the reflector port method or the egress port method.



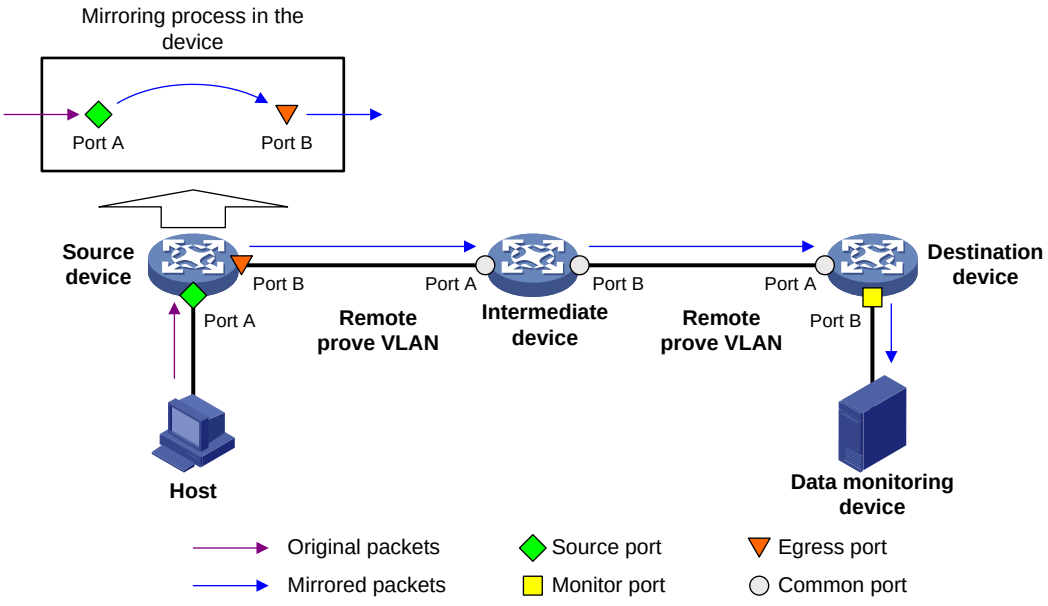
Reflector port method

In Layer 2 remote port mirroring that uses the reflector port method, packets are mirrored as follows:

1. The source device copies packets received on the mirroring sources to the reflector port.
2. The reflector port broadcasts the mirrored packets in the remote probe VLAN.
3. The intermediate devices transmit the mirrored packets to the destination device through the remote probe VLAN.
4. Upon receiving the mirrored packets, the destination device determines whether the ID of the mirrored packets is the same as the remote probe VLAN ID. If the two VLAN IDs match, the

destination device forwards the mirrored packets to the data monitoring device through the monitor port.

Figure 2 Layer 2 remote port mirroring implementation through the reflector port method



Egress port method

In Layer 2 remote port mirroring that uses the egress port method, packets are mirrored as follows:

1. The source device copies packets received on the mirroring sources to the egress port.
2. The egress port forwards the mirrored packets to the intermediate devices.
3. The intermediate devices flood the mirrored packets in the remote probe VLAN and transmit the mirrored packets to the destination device.
4. Upon receiving the mirrored packets, the destination device determines whether the ID of the mirrored packets is the same as the remote probe VLAN ID. If the two VLAN IDs match, the destination device forwards the mirrored packets to the data monitoring device through the monitor port.

Figure 3 Layer 2 remote port mirroring implementation through the egress port method

Restrictions and guidelines: Port mirroring configuration

The reflector port method for Layer 2 remote port mirroring can be used to implement local port mirroring with multiple data monitoring devices.

In the reflector port method, the reflector port broadcasts mirrored packets in the remote probe VLAN. By assigning the ports that connect to data monitoring devices to the remote probe VLAN, you can implement local port mirroring to mirror packets to multiple data monitoring devices. The egress port method cannot implement local port mirroring in this way.

Configuring local port mirroring

Restrictions and guidelines for local port mirroring configuration

A local mirroring group takes effect only after it is configured with the monitor port and mirroring sources.

Local port mirroring tasks at a glance

To configure local port mirroring, perform the following tasks:

1. Configuring mirroring sources
2. Configuring the monitor port

Creating a local mirroring group

1. Enter system view.

system-view

2. Create a local mirroring group.
   mirroring-group *group-id* **local**

Configuring mirroring sources

Restrictions and guidelines for mirroring source configuration

When you configure source ports for a local mirroring group, follow these restrictions and guidelines:

- A mirroring group can contain multiple source ports.
- A port can act as a source port for multiple mirroring groups.
- A source port cannot be configured as a reflector port, egress port, or monitor port.

Configuring source ports

- Configure source ports in system view:
  a. Enter system view.
     system-view
  b. Configure source ports for a local mirroring group.
     mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }
     By default, no source port is configured for a local mirroring group.
- Configure source ports in interface view:
  a. Enter system view.
     system-view
  b. Enter interface view.
     interface *interface-type interface-number*
  c. Configure the port as a source port for a local mirroring group.
     mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }
     By default, a port does not act as a source port for any local mirroring groups.

Configuring the monitor port

Restrictions and guidelines

Do not enable the spanning tree feature on the monitor port.

Only one monitor port can be specified for a local mirroring group.

For a Layer 2 aggregate interface configured as the monitor port of a mirroring group, do not configure its member ports as source ports of the mirroring group.

Use a monitor port only for port mirroring, so the data monitoring device receives only the mirrored traffic.

Procedure

- Configure the monitor port in system view:
  a. Enter system view.
     system-view
  b. Configure the monitor port for a local mirroring group.

mirroring-group *group-id* **monitor-port** *interface-type interface-number*

By default, no monitor port is configured for a local mirroring group.

- Configure the monitor port in interface view:
  a. Enter system view.
     system-view
  b. Enter interface view.
     interface *interface-type interface-number*
  c. Configure the port as the monitor port for a mirroring group.
     mirroring-group *group-id* **monitor-port**
     By default, a port does not act as the monitor port for any local mirroring groups.

Configuring local port mirroring group with multiple monitoring devices

About local port mirroring with multiple monitoring devices

To monitor interesting traffic passing through a device on multiple directly connected data monitoring devices, configure local port mirroring with a remote probe VLAN as follows:

1. Configure a remote source group on the device.
2. Configure mirroring sources and a reflector port for the remote source group.
3. Specify a VLAN as the remote probe VLAN and assign the ports connecting to the data monitoring devices to the VLAN.

This configuration enables the device to copy packets received on the mirroring sources to the reflector port, which broadcasts the packets in the remote probe VLAN. The packets are then sent out of the member ports of the remote probe VLAN to the data monitoring devices.

Restrictions and guidelines

The reflector port must be a port not in use. Do not connect a network cable to the reflector port.

When a port is configured as a reflector port, the port restores to the factory default settings. You cannot configure other features on the reflector port.

Do not assign a source port of a mirroring group to the remote probe VLAN of the mirroring group.

A VLAN can act as the remote probe VLAN for only one remote source group. As a best practice, use the VLAN for port mirroring exclusively. Do not create a VLAN interface for the VLAN or configure other features for the VLAN.

The remote probe VLAN must be a static VLAN.

To delete a VLAN that has been configured as the remote probe VLAN for a mirroring group, remove the remote probe VLAN from the mirroring group first.

Procedure

1. Enter system view.
   system-view
2. Create a remote source group.
   mirroring-group *group-id* **remote-source**
3. Configure mirroring sources for the remote source group. Choose one option as needed:
   - Configure mirroring ports in system view.

mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }

- Execute the following commands in sequence to enter interface view and then configure the interface as a source port.

  interface *interface-type interface-number*

  mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }

  quit

4. Configure the reflector port for the remote source group.

   mirroring-group *group-id* **reflector-port** *reflector-port*

   By default, no reflector port is configured for a remote source group.
5. Create a VLAN and enter its view.

   vlan *vlan-id*
6. Assign the ports that connect to the data monitoring devices to the VLAN.

   port *interface-list*

   By default, a VLAN does not contain any ports.
7. Return to system view.

   quit
8. Specify the VLAN as the remote probe VLAN for the remote source group.

   mirroring-group *group-id* **remote-probe vlan** *vlan-id*

   By default, no remote probe VLAN is configured for a remote source group.

Configuring Layer 2 remote port mirroring

Restrictions and guidelines for Layer 2 remote port mirroring configuration

To ensure successful traffic mirroring, configure devices in the order of the destination device, the intermediate devices, and the source device.

If intermediate devices exist, configure the intermediate devices to allow the remote probe VLAN to pass through.

For a mirrored packet to successfully arrive at the remote destination device, make sure its VLAN ID is not removed or changed.

Do not configure both MVRP and Layer 2 remote port mirroring. Otherwise, MVRP might register the remote probe VLAN with incorrect ports, which would cause the monitor port to receive undesired copies. For more information about MVRP, see *Layer 2—LAN Switching Configuration Guide*.

To monitor the bidirectional traffic of a source port, disable MAC address learning for the remote probe VLAN on the source, intermediate, and destination devices. For more information about MAC address learning, see *Layer 2—LAN Switching Configuration Guide*.

Layer 2 remote port mirroring with reflector port configuration task list

Configuring the destination device

1. Creating a remote destination group

2. Configuring the monitor port
3. Configuring the remote probe VLAN
4. Assigning the monitor port to the remote probe VLAN

Configuring the source device

1. Creating a remote source group
2. Configuring mirroring sources
3. Configuring the reflector port
4. Configuring the remote probe VLAN

Layer 2 remote port mirroring with egress port configuration task list

Configuring the destination device

1. Creating a remote destination group
2. Configuring the monitor port
3. Configuring the remote probe VLAN
4. Assigning the monitor port to the remote probe VLAN

Configuring the source device

1. Creating a remote source group
2. Configuring mirroring sources
3. Configuring the egress port
4. Configuring the remote probe VLAN

Creating a remote destination group

Restrictions and guidelines

Perform this task on the destination device only.

Procedure

1. Enter system view.
   `system-view`
2. Create a remote destination group.
   `mirroring-group` *`group-id`* **`remote-destination`**

Configuring the monitor port

Restrictions and guidelines for monitor port configuration

Perform this task on the destination device only.

Do not enable the spanning tree feature on the monitor port.

For a Layer 2 aggregate interface configured as the monitor port of a mirroring group, do not configure its member ports as source ports of the mirroring group.

Use a monitor port only for port mirroring, so the data monitoring device receives only the mirrored traffic.

A monitor port can belong to only one mirroring group.

Only one monitor port can be specified for a remote destination group.

Configuring the monitor port in system view

1. Enter system view.
   system-view
2. Configure the monitor port for a remote destination group.
   mirroring-group *group-id* **monitor-port** *interface-type interface-number*
   By default, no monitor port is configured for a remote destination group.

Configuring the monitor port in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the port as the monitor port for a remote destination group.
   mirroring-group *group-id* **monitor-port**
   By default, a port does not act as the monitor port for any remote destination groups.

Configuring the remote probe VLAN

Restrictions and guidelines

This task is required on the both the source and destination devices.

Only an existing static VLAN can be configured as a remote probe VLAN.

When a VLAN is configured as a remote probe VLAN, use the remote probe VLAN for port mirroring exclusively.

Configure the same remote probe VLAN for the remote source group and the remote destination group.

Procedure

1. Enter system view.
   system-view
2. Configure the remote probe VLAN for the remote source or destination group.
   mirroring-group *group-id* **remote-probe vlan** *vlan-id*
   By default, no remote probe VLAN is configured for a remote source or destination group.

Assigning the monitor port to the remote probe VLAN

Restrictions and guidelines

Perform this task on the destination device only.

Procedure

1. Enter system view.
   system-view
2. Enter the interface view of the monitor port.
   interface *interface-type interface-number*
3. Assign the port to the remote probe VLAN.

- Assign an access port to the remote probe VLAN.
  port access vlan *vlan-id*
- Assign a trunk port to the remote probe VLAN.
  port trunk permit vlan *vlan-id*
- Assign a hybrid port to the remote probe VLAN.
  port hybrid vlan *vlan-id* { **tagged** | **untagged** }

For more information about the **port access vlan**, **port trunk permit vlan**, and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

Creating a remote source group

Restrictions and guidelines

Perform this task on the source device only.

Procedure

1. Enter system view.
   system-view
2. Create a remote source group.
   mirroring-group *group-id* **remote-source**

Configuring mirroring sources

Restrictions and guidelines for mirroring source configuration

Perform this task on the source device only.

When you configure source ports for a remote source group, follow these restrictions and guidelines:

- Do not assign a source port of a mirroring group to the remote probe VLAN of the mirroring group.
- A mirroring group can contain multiple source ports.
- A port can act as a source port for multiple mirroring groups.
- A source port cannot be configured as a reflector port, monitor port, or egress port.

Configuring source ports

- Configure source ports in system view:
  a. Enter system view.
     system-view
  b. Configure source ports for a remote source group.
     mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }
     By default, no source port is configured for a remote source group.
- Configure source ports in interface view:
  a. Enter system view.
     system-view
  b. Enter interface view.
     interface *interface-type interface-number*
  c. Configure the port as a source port for a remote source group.

mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }

By default, a port does not act as a source port for any remote source groups.

Configuring the reflector port

Restrictions and guidelines for reflector port configuration

Perform this task on the source device only.

A remote source group supports only one reflector port.

Configuring the reflector port in system view

1. Enter system view.

   system-view

2. Configure the reflector port for a remote source group.

   mirroring-group *group-id* **reflector-port** *interface-type interface-number*

CAUTION:

- The port to be configured as a reflector port must be a port not in use. Do not connect a network cable to a reflector port.
- When a port is configured as a reflector port, the default settings of the port are automatically restored. You cannot configure other features on the reflector port.
- If an IRF port is bound to only one physical interface, do not configure the physical interface as a reflector port. Otherwise, the IRF might split.

By default, no reflector port is configured for a remote source group.

Configuring the reflector port in interface view

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the port as the reflector port for a remote source group.

   mirroring-group *group-id* **reflector-port**

CAUTION:

- The port to be configured as a reflector port must be a port not in use. Do not connect a network cable to a reflector port.
- When a port is configured as a reflector port, the default settings of the port are automatically restored. You cannot configure other features on the reflector port.
- If an IRF port is bound to only one physical interface, do not configure the physical interface as a reflector port. Otherwise, the IRF might split.

By default, a port does not act as the reflector port for any remote source groups.

Configuring the egress port

Restrictions and guidelines for egress port configuration

Perform this task on the source device only.

Disable the following features on the egress port:

- Spanning tree.
- 802.1X.
- Static ARP.
- MAC address learning.

A port of an existing mirroring group cannot be configured as an egress port.

A mirroring group supports only one egress port.

Configuring the egress port in system view

1. Enter system view.
   system-view
2. Configure the egress port for a remote source group.
   mirroring-group *group-id* **monitor-egress** *interface-type interface-number*
   By default, no egress port is configured for a remote source group.
3. Enter the egress port view.
   interface *interface-type interface-number*
4. Assign the egress port to the remote probe VLAN.
   - Assign a trunk port to the remote probe VLAN.
     port trunk permit vlan *vlan-id*
   - Assign a hybrid port to the remote probe VLAN.
     port hybrid vlan *vlan-id* { **tagged** | **untagged** }

   For more information about the **port trunk permit vlan** and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

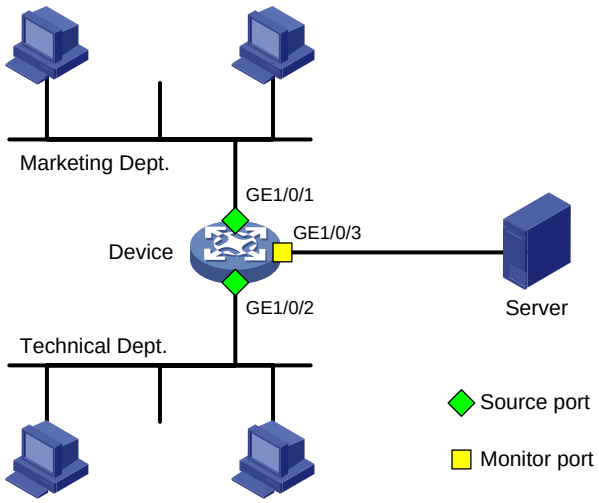
Configuring the egress port in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the port as the egress port for a remote source group.
   mirroring-group *group-id* **monitor-egress**
   By default, a port does not act as the egress port for any remote source groups.

Display and maintenance commands for port mirroring

Execute **display** commands in any view.

Task	Command
Display mirroring group information.	**display mirroring-group** { *group-id* | **all** | **local** | **remote-destination** | **remote-source** }



Port mirroring configuration examples

Example: Configuring local port mirroring (in source port mode)

Network configuration

As shown in Figure 4, configure local port mirroring in source port mode to enable the server to monitor the bidirectional traffic of the two departments.

Figure 4 Network diagram

Procedure

Create local mirroring group 1.

```
<Device> system-view
[Device] mirroring-group 1 local
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as source ports for local mirroring group 1.

```
[Device] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 gigabitethernet 1/0/2
both
```

Configure GigabitEthernet 1/0/3 as the monitor port for local mirroring group 1.

```
[Device] mirroring-group 1 monitor-port gigabitethernet 1/0/3
```

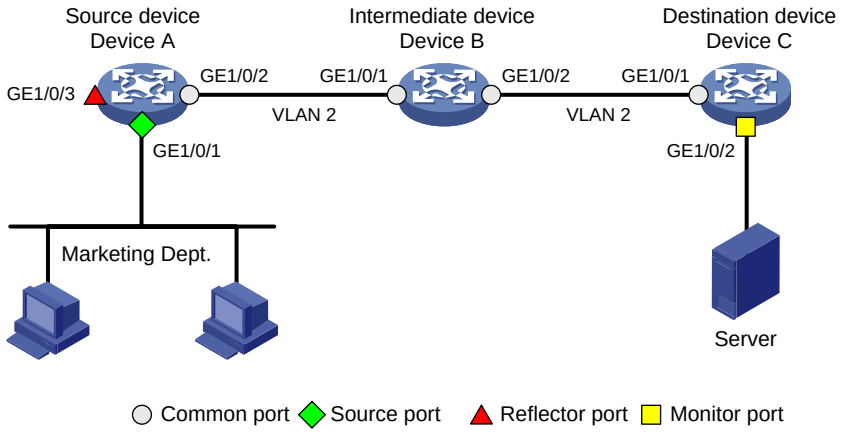
Disable the spanning tree feature on the monitor port (GigabitEthernet 1/0/3).

```
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] undo stp enable
[Device-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify the mirroring group configuration.

```
[Device] display mirroring-group all
Mirroring group 1:
    Type: Local
    Status: Active
    Mirroring port:
```



```
    GigabitEthernet1/0/1   Both
    GigabitEthernet1/0/2   Both
Monitor port: GigabitEthernet1/0/3
```

Example: Configuring Layer 2 remote port mirroring (with reflector port)

Network configuration

As shown in Figure 5, configure Layer 2 remote port mirroring to enable the server to monitor the bidirectional traffic of the Marketing Department.

Figure 5 Network diagram

Procedure

1. Configure Device C (the destination device):

   # Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

   ```
   <DeviceC> system-view
   [DeviceC] interface gigabitethernet 1/0/1
   [DeviceC-GigabitEthernet1/0/1] port link-type trunk
   [DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 2
   [DeviceC-GigabitEthernet1/0/1] quit
   ```

   # Create a remote destination group.

   ```
   [DeviceC] mirroring-group 2 remote-destination
   ```

   # Create VLAN 2.

   ```
   [DeviceC] vlan 2
   ```

   # Disable MAC address learning for VLAN 2.

   ```
   [DeviceC-vlan2] undo mac-address mac-learning enable
   [DeviceC-vlan2] quit
   ```

   # Configure VLAN 2 as the remote probe VLAN for the mirroring group.

   ```
   [DeviceC] mirroring-group 2 remote-probe vlan 2
   ```

   # Configure GigabitEthernet 1/0/2 as the monitor port for the mirroring group.

   ```
   [DeviceC] interface gigabitethernet 1/0/2
   [DeviceC-GigabitEthernet1/0/2] mirroring-group 2 monitor-port
   ```

   # Disable the spanning tree feature on GigabitEthernet 1/0/2.

   ```
   [DeviceC-GigabitEthernet1/0/2] undo stp enable
   ```

Assign GigabitEthernet 1/0/2 to VLAN 2.

```
[DeviceC-GigabitEthernet1/0/2] port access vlan 2
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device B (the intermediate device):

Create VLAN 2.

```
<DeviceB> system-view
[DeviceB] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceB-vlan2] undo mac-address mac-learning enable
[DeviceB-vlan2] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device A (the source device):

Create a remote source group.

```
<DeviceA> system-view
[DeviceA] mirroring-group 1 remote-source
```

Create VLAN 2.

```
[DeviceA] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceA-vlan2] undo mac-address mac-learning enable
[DeviceA-vlan2] quit
```

Configure VLAN 2 as the remote probe VLAN for the mirroring group.

```
[DeviceA] mirroring-group 1 remote-probe vlan 2
```

Configure GigabitEthernet 1/0/1 as a source port for the mirroring group.

```
[DeviceA] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 both
```

Configure GigabitEthernet 1/0/3 as the reflector port for the mirroring group.

```
[DeviceA] mirroring-group 1 reflector-port gigabitethernet 1/0/3
This operation may delete all settings made on the interface. Continue? [Y/N]: y
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceA-GigabitEthernet1/0/2] quit
```

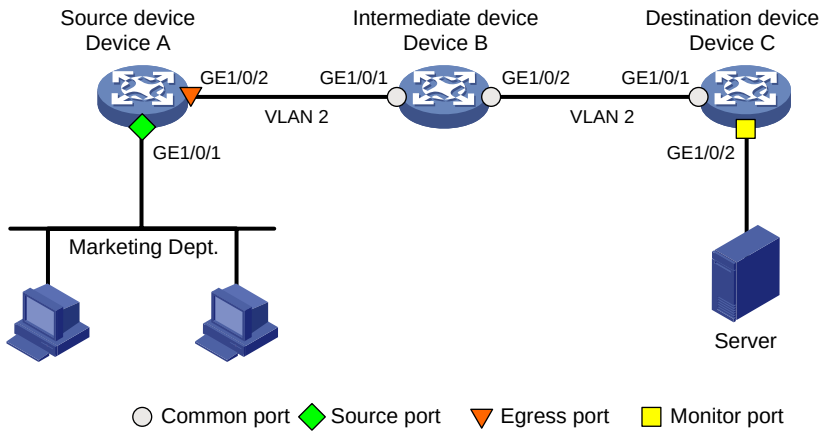
Verifying the configuration

Verify the mirroring group configuration on Device C.

```
[DeviceC] display mirroring-group all
Mirroring group 2:
    Type: Remote destination
    Status: Active
```

```
    Monitor port: GigabitEthernet1/0/2
    Remote probe VLAN: 2
```

Verify the mirroring group configuration on Device A.



```
[DeviceA] display mirroring-group all
Mirroring group 1:
    Type: Remote source
    Status: Active
    Mirroring port:
        GigabitEthernet1/0/1  Both
    Reflector port: GigabitEthernet1/0/3
    Remote probe VLAN: 2
```

Example: Configuring Layer 2 remote port mirroring (with egress port)

Network configuration

On the Layer 2 network shown in Figure 6, configure Layer 2 remote port mirroring to enable the server to monitor the bidirectional traffic of the Marketing Department.

Figure 6 Network diagram

Procedure

1. Configure Device C (the destination device):

   # Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

   ```
   <DeviceC> system-view
   [DeviceC] interface gigabitethernet 1/0/1
   [DeviceC-GigabitEthernet1/0/1] port link-type trunk
   [DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 2
   [DeviceC-GigabitEthernet1/0/1] quit
   ```

   # Create a remote destination group.

   ```
   [DeviceC] mirroring-group 2 remote-destination
   ```

   # Create VLAN 2.

   ```
   [DeviceC] vlan 2
   ```

   # Disable MAC address learning for VLAN 2.

   ```
   [DeviceC-vlan2] undo mac-address mac-learning enable
   ```

```
[DeviceC-vlan2] quit
```

Configure VLAN 2 as the remote probe VLAN for the mirroring group.

```
[DeviceC] mirroring-group 2 remote-probe vlan 2
```

Configure GigabitEthernet 1/0/2 as the monitor port for the mirroring group.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] mirroring-group 2 monitor-port
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceC-GigabitEthernet1/0/2] undo stp enable
```

Assign GigabitEthernet 1/0/2 to VLAN 2 as an access port.

```
[DeviceC-GigabitEthernet1/0/2] port access vlan 2
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device B (the intermediate device):

Create VLAN 2.

```
<DeviceB> system-view
[DeviceB] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceB-vlan2] undo mac-address mac-learning enable
[DeviceB-vlan2] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device A (the source device):

Create a remote source group.

```
<DeviceA> system-view
[DeviceA] mirroring-group 1 remote-source
```

Create VLAN 2.

```
[DeviceA] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceA-vlan2] undo mac-address mac-learning enable
[DeviceA-vlan2] quit
```

Configure VLAN 2 as the remote probe VLAN of the mirroring group.

```
[DeviceA] mirroring-group 1 remote-probe vlan 2
```

Configure GigabitEthernet 1/0/1 as a source port for the mirroring group.

```
[DeviceA] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 both
```

Configure GigabitEthernet 1/0/2 as the egress port for the mirroring group.

```
[DeviceA] mirroring-group 1 monitor-egress gigabitethernet 1/0/2
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 2
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Verify the mirroring group configuration on Device C.

```
[DeviceC] display mirroring-group all
Mirroring group 2:
    Type: Remote destination
    Status: Active
    Monitor port: GigabitEthernet1/0/2
    Remote probe VLAN: 2
```

Verify the mirroring group configuration on Device A.

```
[DeviceA] display mirroring-group all
Mirroring group 1:
    Type: Remote source
    Status: Active
    Mirroring port:
        GigabitEthernet1/0/1  Both
    Monitor egress port: GigabitEthernet1/0/2
    Remote probe VLAN: 2
```

Configuring flow mirroring

About flow mirroring

Flow mirroring copies packets matching a class to a destination for packet analyzing and monitoring. It is implemented through QoS.

To implement flow mirroring through QoS, perform the following tasks:

- Define traffic classes and configure match criteria to classify packets to be mirrored. Flow mirroring allows you to flexibly classify packets to be analyzed by defining match criteria.
- Configure traffic behaviors to mirror the matching packets to the specified destination.

You can configure an action to mirror the matching packets to one of the following destinations:

- **Interface**—The matching packets are copied to an interface and then forwarded to a data monitoring device for analysis.
- **CPU**—The matching packets are copied to the CPU of an IRF member device. The CPU analyzes the packets or delivers them to upper layers.

For more information about QoS policies, traffic classes, and traffic behaviors, see *ACL and QoS Configuration Guide*.

Restrictions and guidelines: Flow mirroring configuration

For information about the configuration commands except the **`mirror-to`** command, see *ACL and QoS Command Reference*.

Flow mirroring tasks at a glance

To configure flow mirroring, perform the following tasks:

1. Configuring a traffic class

   A traffic class defines the criteria that filters the traffic to be mirrored.
2. Configuring a traffic behavior

   A traffic behavior specifies mirroring destinations.
3. Configuring a QoS policy
4. Applying a QoS policy

   Choose one of the following tasks:
   - Applying a QoS policy to an interface
   - Applying a QoS policy to a VLAN
   - Applying a QoS policy globally

Configuring a traffic class

1. Enter system view.

   `system-view`
2. Create a class and enter class view.

traffic classifier *classifier-name* [**operator** { **and** | **or** }]

3. Configure match criteria.
   if-match *match-criteria*
   By default, no match criterion is configured in a traffic class.
4. (Optional.) Display traffic class information.
   display traffic classifier
   This command is available in any view.

Configuring a traffic behavior

Procedure

1. Enter system view.
   system-view
2. Create a traffic behavior and enter traffic behavior view.
   traffic behavior *behavior-name*
3. Configure mirroring destinations for the traffic behavior. Choose one option as needed:
   - Mirror traffic to interfaces.
     mirror-to interface *interface-type interface-number*
     By default, no mirroring actions exist to mirror traffic to interfaces.
   - Mirror traffic to the CPU.
     mirror-to cpu
     By default, no mirroring actions exist to mirror traffic to the CPU.
4. (Optional.) Display traffic behavior configuration.
   display traffic behavior
   This command is available in any view.

Configuring a QoS policy

1. Enter system view.
   system-view
2. Create a QoS policy and enter QoS policy view.
   qos policy *policy-name*
3. Associate a class with a traffic behavior in the QoS policy.
   classifier *classifier-name* **behavior** *behavior-name*
   By default, no traffic behavior is associated with a class.
4. (Optional.) Display QoS policy configuration.
   display qos policy
   This command is available in any view.

Applying a QoS policy

Applying a QoS policy to an interface

Restrictions and guidelines

You can apply a QoS policy to an interface to mirror the traffic of the interface.

A policy can be applied to multiple interfaces.

A QoS policy cannot be applied in the outbound direction of an interface. In the inbound direction of an interface, only one QoS policy can be applied.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Apply a policy to the interface.
   qos apply policy *policy-name* **inbound**
4. (Optional.) Display the QoS policy applied to the interface.
   display qos policy interface
   This command is available in any view.

Applying a QoS policy to a VLAN

Restrictions and guidelines

You can apply a QoS policy to a VLAN to mirror the traffic on all ports in the VLAN.

Procedure

1. Enter system view.
   system-view
2. Apply a QoS policy to a VLAN.
   qos vlan-policy *policy-name* **vlan** *vlan-id-list* **inbound**
3. (Optional.) Display the QoS policy applied to the VLAN.
   display qos vlan-policy
   This command is available in any view.

Applying a QoS policy globally

Restrictions and guidelines

You can apply a QoS policy globally to mirror the traffic on all ports.

Procedure

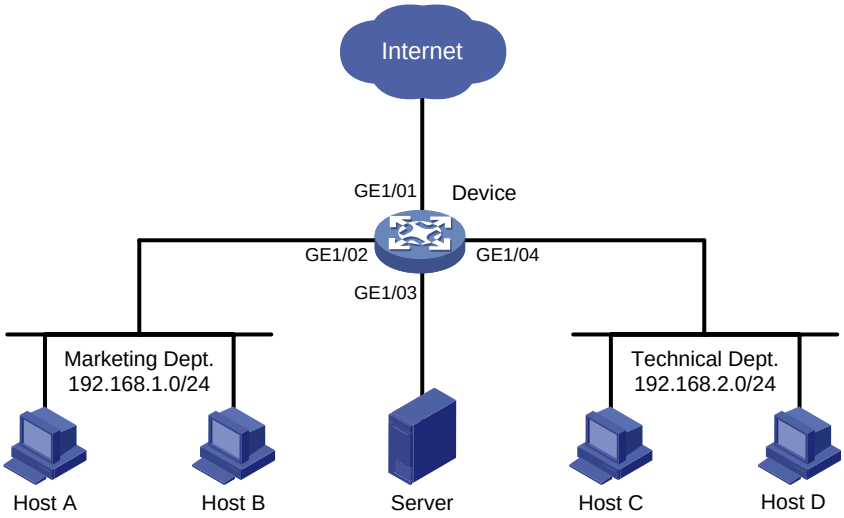
1. Enter system view.
   system-view
2. Apply a QoS policy globally.
   qos apply policy *policy-name* **global inbound**

3. (Optional.) Display global QoS policies.

   display qos policy global

   This command is available in any view.

Flow mirroring configuration examples



Example: Configuring flow mirroring

Network configuration

As shown in Figure 7, configure flow mirroring so that the server can monitor the following traffic:

- All traffic that the Technical Department sends to access the Internet.
- IP traffic that the Technical Department sends to the Marketing Department during working hours (8:00 to 18:00) on weekdays.

Figure 7 Network diagram

Procedure

Create working hour range **work**, in which working hours are from 8:00 to 18:00 on weekdays.

```
<Device> system-view
[Device] time-range work 8:00 to 18:00 working-day
```

Create IPv4 advanced ACL 3000 to allow packets from the Technical Department to access the Internet and the Marketing Department during working hours.

```
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule permit tcp source 192.168.2.0 0.0.0.255 destination-port
eq www
[Device-acl-ipv4-adv-3000] rule permit ip source 192.168.2.0 0.0.0.255 destination
192.168.1.0 0.0.0.255 time-range work
[Device-acl-ipv4-adv-3000] quit
```

Create traffic class **tech_c**, and configure the match criterion as ACL 3000.

```
[Device] traffic classifier tech_c
[Device-classifier-tech_c] if-match acl 3000
[Device-classifier-tech_c] quit
```

Create traffic behavior **tech_b**, configure the action of mirroring traffic to GigabitEthernet 1/0/3.

```
[Device] traffic behavior tech_b
[Device-behavior-tech_b] mirror-to interface gigabitethernet 1/0/3
[Device-behavior-tech_b] quit
```

Create QoS policy **tech_p**, and associate traffic class **tech_c** with traffic behavior **tech_b** in the QoS policy.

```
[Device] qos policy tech_p
[Device-qospolicy-tech_p] classifier tech_c behavior tech_b
[Device-qospolicy-tech_p] quit
```

Apply QoS policy **tech_p** to the incoming packets of GigabitEthernet 1/0/4.

```
[Device] interface gigabitethernet 1/0/4
[Device-GigabitEthernet1/0/4] qos apply policy tech_p inbound
[Device-GigabitEthernet1/0/4] quit
```

Verifying the configuration

Verify that the server can monitor the following traffic:

- All traffic sent by the Technical Department to access the Internet.
- IP traffic that the Technical Department sends to the Marketing Department during working hours on weekdays.

(Details not shown.)

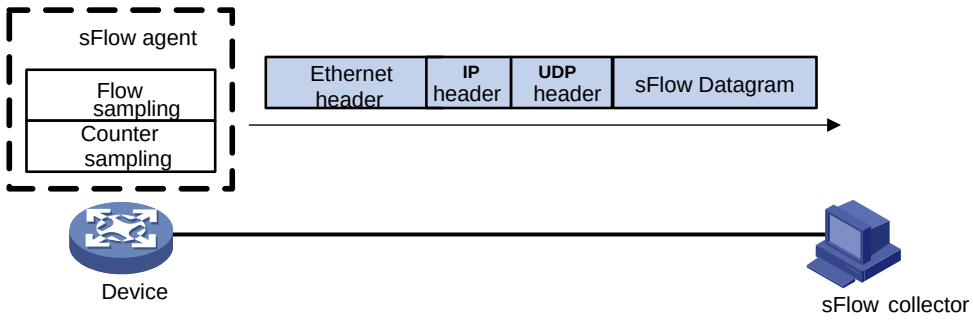
Configuring sFlow

About sFlow

sFlow is a traffic monitoring technology.

As shown in Figure 1, the sFlow system involves an sFlow agent embedded in a device and a remote sFlow collector. The sFlow agent collects interface counter information and packet information and encapsulates the sampled information in sFlow packets. When the sFlow packet buffer is full, or the aging timer (fixed to 1 second) expires, the sFlow agent performs the following actions:

- Encapsulates the sFlow packets in the UDP datagrams.
- Sends the UDP datagrams to the specified sFlow collector.



The sFlow collector analyzes the information and displays the results. One sFlow collector can monitor multiple sFlow agents.

sFlow provides the following sampling mechanisms:

- **Flow sampling**—Obtains packet information.
- **Counter sampling**—Obtains interface counter information.

sFlow can use flow sampling and counter sampling at the same time.

Figure 1 sFlow system

Protocols and standards

- RFC 3176, *InMon Corporation's sFlow: A Method for Monitoring Traffic in Switched and Routed Networks*
- sFlow.org, *sFlow Version 5*

Configuring basic sFlow information

Restrictions and guidelines

As a best practice, manually configure an IP address for the sFlow agent. The device periodically checks whether the sFlow agent has an IP address. If the sFlow agent does not have an IP address, the device automatically selects an IPv4 address for the sFlow agent but does not save the IPv4 address in the configuration file.

Only one IP address can be configured for the sFlow agent on the device, and a newly configured IP address overwrites the existing one.

Procedure

1. Enter system view.

   system-view

2. Configure an IP address for the sFlow agent.

   sflow agent { **ip** *ipv4-address* | **ipv6** *ipv6-address* }

   By default, no IP address is configured for the sFlow agent.

3. Configure the sFlow collector information.

   sflow collector *collector-id* [**vpn-instance** *vpn-instance-name*] { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number* | **datagram-size** *size* | **time-out** *seconds* | **description** *string*] *

   By default, no sFlow collector information is configured.

4. Specify the source IP address of sFlow packets.

   sflow source { **ip** *ipv4-address* | **ipv6** *ipv6-address* } *

   By default, the source IP address is determined by routing.

Configuring flow sampling

About this task

Perform this task to configure flow sampling on an Ethernet interface. The sFlow agent performs the following tasks:

1. Samples packets on that interface according to the configured parameters.
2. Encapsulates the packets into sFlow packets.
3. Encapsulates the sFlow packets in the UDP packets and sends the UDP packets to the specified sFlow collector.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view.

   interface *interface-type interface-number*

3. (Optional.) Set the flow sampling mode.

   sflow sampling-mode determine | **random**

   By default, random sampling is used.

4. Enable flow sampling and specify the number of packets out of which flow sampling samples a packet on the interface.

   sflow sampling-rate *rate*

   By default, flow sampling is disabled.

   As a best practice, set the sampling interval to 2^n that is greater than or equal to 8192, for example, 32768.

5. (Optional.) Set the maximum number of bytes (starting from the packet header) that flow sampling can copy per packet.

   sflow flow max-header *length*

   The default setting is 128 bytes.

   As a best practice, use the default setting.

6. Specify the sFlow instance and sFlow collector for flow sampling.

   sflow flow [**instance** *instance-id*] **collector** *collector-id*

By default, no sFlow instance or sFlow collector is specified for flow sampling.

Configuring counter sampling

About this task

Perform this task to configure counter sampling on an Ethernet interface. The sFlow agent performs the following tasks:

1. Periodically collects the counter information on that interface.
2. Encapsulates the counter information into sFlow packets.
3. Encapsulates the sFlow packets in the UDP packets and sends the UDP packets to the specified sFlow collector.

Procedure

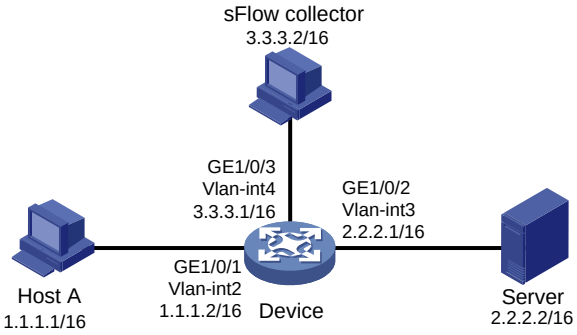
1. Enter system view.
   `system-view`
2. Enter Layer 2 Ethernet interface view.
   `interface` *`interface-type interface-number`*
3. Enable counter sampling and set the counter sampling interval.
   `sflow counter interval` *`interval`*
   By default, counter sampling is disabled.
4. Specify the sFlow instance and sFlow collector for counter sampling.
   `sflow counter` [**`instance`** *`instance-id`*] **`collector`** *`collector-id`*
   By default, no sFlow instance or sFlow collector is specified for counter sampling.

Display and maintenance commands for sFlow

Execute **`display`** commands in any view.

Task	Command
Display sFlow configuration.	**`display sflow`**

sFlow configuration examples



Example: Configuring sFlow

Network configuration

As shown in Figure 2, perform the following tasks:

- Configure flow sampling in random mode and counter sampling on GigabitEthernet 1/0/1 of the device to monitor traffic on the port.
- Configure the device to send sampled information in sFlow packets through GigabitEthernet 1/0/3 to the sFlow collector.

Figure 2 Network diagram

Procedure

1. Configure VLANs, assign Ethernet interfaces to VLANs, and configure IP addresses and subnet masks for VLAN interfaces, as shown in Figure 2. (Details not shown.)
2. Configure the sFlow agent and configure information about the sFlow collector:

   # Configure the IP address for the sFlow agent.

   ```
   <Device> system-view
   [Device] sflow agent ip 3.3.3.1
   ```

   # Configure information about the sFlow collector. Specify the sFlow collector ID as 1, IP address as 3.3.3.2, port number as 6343 (default), and description as **netserver**.

   ```
   [Device] sflow collector 1 ip 3.3.3.2 description netserver
   ```

3. Configure counter sampling:

   # Enable counter sampling and set the counter sampling interval to 120 seconds on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] sflow counter interval 120
   ```

   # Specify sFlow collector 1 for counter sampling.

   ```
   [Device-GigabitEthernet1/0/1] sflow counter collector 1
   ```

4. Configure flow sampling:

   # Enable flow sampling and set the flow sampling mode to random and sampling interval to 32767.

   ```
   [Device-GigabitEthernet1/0/1] sflow sampling-mode random
   [Device-GigabitEthernet1/0/1] sflow sampling-rate 32767
   ```

   # Specify sFlow collector 1 for flow sampling.

   ```
   [Device-GigabitEthernet1/0/1] sflow flow collector 1
   ```

Verifying the configuration

Verify the following items:

- GigabitEthernet 1/0/1 enabled with sFlow is active.
- The counter sampling interval is 120 seconds.
- The flow sampling interval is 32767 (one packet is sampled from every 32767 packets).

```
[Device-GigabitEthernet1/0/1] display sflow
sFlow datagram version: 5
Global information:
Agent IP: 3.3.3.1(CLI)
Source address:
Collector information:
```

```
ID    IP              Port  Aging      Size VPN-instance Description
1     3.3.3.2         6343  N/A        1400              netserver
Port counter sampling information:
Interface   Instance   CID   Interval(s)
GE1/0/1     1          1     120
Port flow sampling information:
Interface   Instance   FID   MaxHLen Rate       Mode      Status
GE1/0/1        1          1     128     32767      Random    Active
```

Troubleshooting sFlow

The remote sFlow collector cannot receive sFlow packets

Symptom

The remote sFlow collector cannot receive sFlow packets.

Analysis

The possible reasons include:

- The sFlow collector is not specified.
- sFlow is not configured on the interface.
- The IP address of the sFlow collector specified on the sFlow agent is different from that of the remote sFlow collector.
- The physical link between the device and the sFlow collector fails.
- The sFlow collector is bound to a non-existent VPN.
- The length of an sFlow packet is less than the sum of the following two values:
  - The length of the sFlow packet header.
  - The number of bytes that flow sampling can copy per packet.

Solution

To resolve the problem:

1. Use the **`display sflow`** command to verify that sFlow is correctly configured.
2. Verify that a correct IP address is configured for the device to communicate with the sFlow collector.
3. Verify that the physical link between the device and the sFlow collector is up.
4. Verify that the VPN bound to the sFlow collector already exists.
5. Verify that the length of an sFlow packet is greater than the sum of the following two values:
   - The length of the sFlow packet header.
   - The number of bytes (as a best practice, use the default setting) that flow sampling can copy per packet.

Configuring the information center

About the information center

The information center on the device receives logs generated by source modules and outputs logs to different destinations according to log output rules. Based on the logs, you can monitor device performance and troubleshoot network problems.

Figure 1 Information center diagram

Log types

Logs are classified into the following types:

- **Standard system logs**—Record common system information. Unless otherwise specified, the term "logs" in this document refers to standard system logs.
- **Diagnostic logs**—Record debugging messages.
- **Security logs**—Record security information, such as authentication and authorization information.
- **Hidden logs**—Record log information not displayed on the terminal, such as input commands.
- **Trace logs**—Record system tracing and debugging messages, which can be viewed only after the devkit package is installed.

Log levels

Logs are classified into eight severity levels from 0 through 7 in descending order. The information center outputs logs with a severity level that is higher than or equal to the specified level. For example, if you specify a severity level of 6 (informational), logs that have a severity level from 0 to 6 are output.

Table 1 Log levels

Severity value	Level	Description
0	Emergency	The system is unusable. For example, the system authorization has expired.
1	Alert	Action must be taken immediately. For example, traffic on an interface exceeds the upper limit.
2	Critical	Critical condition. For example, the device temperature exceeds the upper limit, the power module fails, or the fan tray fails.
3	Error	Error condition. For example, the link state changes.
4	Warning	Warning condition. For example, an interface is disconnected, or the memory resources are used up.
5	Notification	Normal but significant condition. For example, a terminal logs in to the device, or the device reboots.

Severity value	Level	Description
6	Informational	Informational message. For example, a command or a ping operation is executed.
7	Debugging	Debugging message.

Log destinations

The system outputs logs to the following destinations: console, monitor terminal, log buffer, log host, and log file. Log output destinations are independent and you can configure them after enabling the information center. One log can be sent to multiple destinations.

Default output rules for logs

A log output rule specifies the source modules and severity level of logs that can be output to a destination. Logs matching the output rule are output to the destination. Table 2 shows the default log output rules.

Table 2 Default output rules

Destination	Log source modules	Output switch	Severity
Console	All supported modules	Enabled	Debugging
Monitor terminal	All supported modules	Disabled	Debugging
Log host	All supported modules	Enabled	Informational
Log buffer	All supported modules	Enabled	Informational
Log file	All supported modules	Enabled	Informational

Default output rules for diagnostic logs

Diagnostic logs can only be output to the diagnostic log file, and cannot be filtered by source modules and severity levels. Table 3 shows the default output rule for diagnostic logs.

Table 3 Default output rule for diagnostic logs

Destination	Log source modules	Output switch	Severity
Diagnostic log file	All supported modules	Enabled	Debugging

Default output rules for security logs

Security logs can only be output to the security log file, and cannot be filtered by source modules and severity levels. Table 4 shows the default output rule for security logs.

Table 4 Default output rule for security logs

Destination	Log source modules	Output switch	Severity
Security log file	All supported modules	Disabled	Debugging

Default output rules for hidden logs

Hidden logs can be output to the log host, the log buffer, and the log file. Table 5 shows the default output rules for hidden logs.

Table 5 Default output rules for hidden logs

Destination	Log source modules	Output switch	Severity
Log host	All supported modules	Enabled	Informational
Log buffer	All supported modules	Enabled	Informational
Log file	All supported modules	Enabled	Informational

Default output rules for trace logs

Trace logs can only be output to the trace log file, and cannot be filtered by source modules and severity levels. Table 6 shows the default output rules for trace logs.

Table 6 Default output rules for trace logs

Destination	Log source modules	Output switch	Severity
Trace log file	All supported modules	Enabled	Debugging

Log formats and field descriptions

Log formats

The format of logs varies by output destinations. Table 7 shows the original format of log information, which might be different from what you see. The actual format varies by the log resolution tool used.

Table 7 Log formats

Output destination	Format
Console, monitor terminal, log buffer, or log file	Prefix Timestamp Sysname Module/Level/Mnemonic: Content Example: `%Nov 24 14:21:43:502 2019 Sysname SHELL/5/SHELL_LOGIN: VTY logged in from 192.168.1.26`

Log host	**Non-customized format**:
	<PRI>Timestamp Sysname %%vvModule/Level/Mnemonic: Location; Content
	Example:
	`<190>Nov 24 16:22:21 2019 Sysname %%10SHELL/5/SHELL_LOGIN: -DevIP=1.1.1.1; VTY logged in from 192.168.1.26<190>Nov 24 16:22:21 2016 Sysname %%10 SHELL/5/SHELL_LOGIN: -DevIP=1.1.1.1; VTY logged in from 192.168.1.26`
	CMCC format:
	<PRI>Timestamp Sysname %vvModule/Level/Mnemonic: Location; Content
	`<189>Oct 9 14:59:04 2019 Sysname %10SHELL/5/SHELL_LOGIN: VTY logged in from 192.168.1.21`
	SGCC format:
	<PRI> Timestamp Sysname Devtype Content
	`<189> 2019-03-18 15:39:45 Sysname FW 0 2 admin 10.1.1.1`
	Unicom format:

	<PRI>Timestamp Hostip vvModule/Level/Serial_number: Content Example: `<189>Oct 13 16:48:08 2019 10.1.1.1 10SHELL/5/210231a64jx073000020: VTY logged in from 192.168.1.21`

Log field description

Table 8 Log field description

Field	Description
Prefix (information type)	A log to a destination other than the log host has an identifier in front of the timestamp: • An identifier of percent sign (%) indicates a log with a level equal to or higher than informational. • An identifier of asterisk (*) indicates a debugging log or a trace log. • An identifier of caret (^) indicates a diagnostic log.
PRI (priority)	A log destined for the log host has a priority identifier in front of the timestamp. The priority is calculated by using this formula: facility*8+level, where: • **facility** is the facility name. Facility names local0 through local7 correspond to values 16 through 23. The facility name can be configured using the **`info-center loghost`** command. It is used to identify log sources on the log host, and to query and filter the logs from specific log sources. • **level** is in the range of 0 to 7. See Table 1 for more information about severity levels.
Timestamp	Records the time when the log was generated. Logs sent to the log host and those sent to the other destinations have different timestamp precisions, and their timestamp formats are configured with different commands. For more information, see Table 9 and Table 10.
Hostip	Source IP address of the log. If the **`info-center loghost source`** command is configured, this field displays the IP address of the specified source interface. Otherwise, this field displays the sysname. This field exists only in logs that are sent to the log host in unicom format.
Serial number	Serial number of the device that generated the log. This field exists only in logs that are sent to the log host in unicom format.
Sysname (host name or host IP address)	The sysname is the host name or IP address of the device that generated the log. You can use the **`sysname`** command to modify the name of the device.
%% (vendor ID)	Indicates that the information was generated by an H3C device. This field exists only in logs sent to the log host.
vv (version information)	Identifies the version of the log, and has a value of 10. This field exists only in logs that are sent to the log host.
Module	Specifies the name of the module that generated the log. You can enter the **`info-center source ?`** command in system view to view the module list.
Level	Identifies the level of the log. See Table 1 for more information about severity levels.
Mnemonic	Describes the content of the log. It contains a string of up to 32 characters.
Location	Optional field that identifies the log sender. This field exists only in logs that are sent to the log host in non-customized or CMCC format. The field contains the following information: • **Devlp**—IP address of the log sender. • **Slot**—Member ID of the IRF member device that sent the log.

Field	Description
Devtype	Device type. This field exists only in logs that are sent to the log host in SGCC format.
Content	Provides the content of the log.

Table 9 Timestamp precisions and configuration commands

Item	Destined for the log host	Destined for the console, monitor terminal, log buffer, and log file
Precision	Seconds (default) or milliseconds	Milliseconds
Command used to set the timestamp format	**info-center timestamp loghost**	**info-center timestamp**

Table 10 Description of the timestamp parameters

Timestamp parameters	Description
boot	Time that has elapsed since system startup, in the format of xxx.yyy. xxx represents the higher 32 bits, and yyy represents the lower 32 bits, of milliseconds elapsed. Logs that are sent to all destinations other than a log host support this parameter. **Example**: `%0.109391473 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` 0.109391473 is a timestamp in the **boot** format.
date	Current date and time. • For logs output to a log host, the timestamp can be in the format of MMM DD hh:mm:ss YYYY (accurate to seconds) or MMM DD hh:mm:ss.ms YYYY (accurate to milliseconds). • For logs output to other destinations, the timestamp is in the format of MMM DD hh:mm:ss:ms YYYY. All logs support this parameter. **Example**: `%May 30 05:36:29:579 2019 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` May 30 05:36:29:579 2019 is a timestamp in the **date** format in logs sent to the console.
iso	Timestamp format stipulated in ISO 8601, accurate to seconds (default) or milliseconds. Only logs that are sent to a log host support this parameter. **Example**: `<189>2019-05-30T06:42:44 Sysname %%10FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` 2019-05-30T06:42:44 is a timestamp in the **iso** format accurate to seconds. A timestamp accurate to milliseconds is like 2019-05-30T06:42:44.708.

Timestamp parameters	Description
none	No timestamp is included. All logs support this parameter. **Example**: `% Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` No timestamp is included.
no-year-date	Current date and time without year or millisecond information, in the format of MMM DD hh:mm:ss. Only logs that are sent to a log host support this parameter. **Example**: `<189>May 30 06:44:22 Sysname %%10FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` May 30 06:44:22 is a timestamp in the **`no-year-date`** format.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Information center tasks at a glance

Managing standard system logs

1. Enabling the information center
2. Outputting logs to various destinations

   Choose the following tasks as needed:
   - Outputting logs to the console
   - Outputting logs to the monitor terminal
   - Outputting logs to log hosts
   - Outputting logs to the log buffer
   - Saving logs to the log file
3. (Optional.) Setting the minimum storage period
4. (Optional.) Enabling synchronous information output
5. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
   - Disabling an interface from generating link up or link down logs
6. (Optional.) Enabling SNMP notifications for system logs

Managing hidden logs

1. Enabling the information center

2. Outputting logs to various destinations
   Choose the following tasks as needed:
   - Outputting logs to log hosts
   - Outputting logs to the log buffer
   - Saving logs to the log file
3. (Optional.) Setting the minimum storage period
4. (Optional.) Configuring log suppression
   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module

Managing security logs

1. Enabling the information center
2. (Optional.) Configuring log suppression
   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
3. Managing security logs
   - Saving security logs to the security log file
   - Managing the security log file

Managing diagnostic logs

1. Enabling the information center
2. (Optional.) Configuring log suppression
   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
3. Saving diagnostic logs to the diagnostic log file

Managing trace logs

1. Enabling the information center
2. (Optional.) Configuring log suppression
   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
3. Setting the maximum size of the trace log file

Enabling the information center

About this task

The information center can output logs only after it is enabled.

Procedure

1. Enter system view.
   system-view
2. Enable the information center.
   info-center enable
   The information center is enabled by default.

Outputting logs to various destinations

Outputting logs to the console

Restrictions and guidelines

The **terminal monitor**, **terminal debugging**, and **terminal logging** commands take effect only for the current connection between the terminal and the device. If a new connection is established, the default is restored.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Configure an output rule for sending logs to the console.
   info-center source { *module-name* | **default** } **console** { **deny** | **level** *severity* }
   For information about the default output rules, see "Default output rules for logs."
3. (Optional.) Configure the timestamp format.
   info-center timestamp { **boot** | **date** | **none** }
   The default timestamp format is **date**.
4. Return to user view.
   quit
5. Enable log output to the console.
   terminal monitor
   By default, log output to the console is enabled.
6. Enable output of debugging messages to the console.
   terminal debugging
   By default, output of debugging messages to the console is disabled.
   This command enables output of debugging-level log messages to the console.
7. Set the lowest severity level of logs that can be output to the console.
   terminal logging level *severity*
   The default setting is 6 (informational).

Outputting logs to the monitor terminal

About this task

Monitor terminals refer to terminals that log in to the device through the AUX or VTY line.

Restrictions and guidelines

The **terminal monitor**, **terminal debugging**, and **terminal logging** commands take effect only for the current connection between the terminal and the device. If a new connection is established, the default is restored.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure an output rule for sending logs to the monitor terminal.

   info-center source { *module-name* | **default** } **monitor** { **deny** | **level** *severity* }

   For information about the default output rules, see "Default output rules for logs."

3. (Optional.) Configure the timestamp format.

   info-center timestamp { **boot** | **date** | **none** }

   The default timestamp format is **date**.

4. Return to user view.

   quit

5. Enable log output to the monitor terminal.

   terminal monitor

   By default, log output to the monitor terminal is disabled.

6. Enable output of debugging messages to the monitor terminal.

   terminal debugging

   By default, output of debugging messages to the monitor terminal is disabled.

   This command enables output of debugging-level log messages to the monitor terminal.

7. Set the lowest level of logs that can be output to the monitor terminal.

   terminal logging level *severity*

   The default setting is 6 (informational).

Outputting logs to log hosts

Restrictions and guidelines

The device supports the following methods (in descending order of priority) for outputting logs of a module to designated log hosts:

- Fast log output.

  For information about the modules that support fast log output and how to configure fast log output, see "Configuring fast log output."

- Flow log.

  For information about the modules that support flow log output and how to configure flow log output, see "Configuring flow log."

- Information center.

If you configure multiple log output methods for a module, only the method with the highest priority takes effect.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure a log output filter or a log output rule. Choose one option as needed:

- Configure a log output filter.

  info-center filter *filter-name* { *module-name* | **default** } { **deny** | **level** *severity* }

  You can create multiple log output filters. When specifying a log host, you can apply a log output filter to the log host to control log output.
- Configure a log output rule for the log host output destination.

  info-center source { *module-name* | **default** } **loghost** { **deny** | **level** *severity* }

  For information about the default log output rules for the log host output destination, see "Default output rules for logs."

The system chooses the settings to control log output to a log host in the following order:

a. Log output filter applied to the log host.

b. Log output rules configured for the log host output destination by using the **info-center source** command.

c. Default log output rules (see "Default output rules for logs").

3. (Optional.) Specify a source IP address for logs sent to log hosts.

   info-center loghost source *interface-type interface-number*

   By default, the source IP address of logs sent to log hosts is the primary IP address of their outgoing interfaces.
4. (Optional.) Specify the format in which logs are output to log hosts.

info-center format { **cmcc** | **unicom** }

   By default, logs are output to log hosts in non-customized format.
5. (Optional.) Configure the timestamp format.

   info-center timestamp loghost { **date** [**with-milliseconds**] | **iso** [**with-milliseconds** | **with-timezone**] * | **no-year-date** | **none** }

   The default timestamp format is **date**.
6. Specify a log host and configure related parameters.

   info-center loghost [**vpn-instance** *vpn-instance-name*] { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**dscp** *dscp-value*] [**facility** *local-number*] [**filter** *filter-name*]

   By default, no log hosts or related parameters are specified.

   The value for the *port-number* argument must be the same as the value configured on the log host. Otherwise, the log host cannot receive logs.

Outputting logs to the log buffer

About this task

This feature enables log output to the log buffer. You can use the **display logbuffer** command to display the log buffer information and the buffered logs.

Procedure

1. Enter system view.

   system-view
2. (Optional.) Configure an output rule for sending logs to the log buffer.

   info-center source { *module-name* | **default** } **logbuffer** { **deny** | **level** *severity* }

   For information about the default output rules, see "Default output rules for logs."

3. (Optional.) Configure the timestamp format.

   info-center timestamp { **boot** | **date** | **none** }

   The default timestamp format is **date**.

4. Enable log output to the log buffer.

   info-center logbuffer

   By default, log output to the log buffer is enabled.

5. (Optional.) Set the maximum log buffer size.

   info-center logbuffer size *buffersize*

   By default, a maximum of 512 logs can be buffered.

Saving logs to the log file

About this task

The log file feature enables log output to the log file. The system saves logs from the log file buffer to the log file. After saving logs to the log file, the system clears the log file buffer.

Log saving from the log file buffer to the log file is triggered by the following situations:

- Periodic saving.
- A manual immediate saving of buffered logs to the log file.
- The log file buffer is full.

A log file is automatically created when needed and has a maximum capacity. The log file capacity restrictions are as follows:

- When log file overwrite-protection is enabled and no log file space is available, the device stops saving new logs.

  When log file overwrite-protection is disabled and no log file space or storage device space is available, the system will replace the oldest logs with new logs.

TIP:

- Clean up the storage space of the device regularly to ensure sufficient storage space for the log file feature.
- As a best practice, back up the log files regularly to avoid loss of important logs.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure an output rule for sending logs to the log file.

   info-center source { *module-name* | **default** } **logfile** { **deny** | **level** *severity* }

   For information about the default output rules, see "Default output rules for logs."

3. Enable the log file feature.

   info-center logfile enable

   By default, the log file feature is enabled.

4. (Optional.) Enable log file overwrite-protection.

   info-center logfile overwrite-protection [**all-port-powerdown**]

   By default, log file overwrite-protection is disabled.

   Log file overwrite-protection is supported only in FIPS mode.

5. (Optional.) Set the maximum log file size.

info-center logfile size-quota *size*

By default, the maximum log file size is 10 MB.

6. (Optional.) Specify the log file directory.

   info-center logfile directory *dir-name*

   The default log file directory is **flash:/logfile**.

   This command cannot survive an IRF reboot or a master/subordinate switchover.

7. Save logs in the log file buffer to the log file. Choose one or both options as needed:
   - Configure the automatic log file saving interval.

     info-center logfile frequency *freq-sec*

     The default log file saving interval is 86400 seconds.
   - Immediately save logs from the log file buffer to the log file.

     logfile save

     This command is available in any view.

Setting the minimum storage period

About this task

Use this feature to set the minimum storage period for logs in the log buffer and log file. This feature ensures that logs will not be overwritten by new logs during a set period of time.

By default, when the log buffer or log file is full, new logs will automatically overwrite the oldest logs. After the minimum storage period is set, the system identifies the storage period of a log to determine whether to delete the log. The system current time minus a log's generation time is the log's storage period.

- If the storage period of a log is shorter than or equal to the minimum storage period, the system does not delete the log. The new log will not be saved.
- If the storage period of a log is longer than the minimum storage period, the system deletes the log to save the new log.

Procedure

1. Enter system view.

   system-view

2. Set the log minimum storage period for logs.

   info-center syslog min-age *min-age*

   By default, the log minimum storage period is not set.

Enabling synchronous information output

About this task

System log output interrupts ongoing configuration operations, obscuring previously entered commands. Synchronous information output shows the obscured commands. It also provides a command prompt in command editing mode, or a [Y/N] string in interaction mode so you can continue your operation from where you were stopped.

Procedure

1. Enter system view.

   system-view

2. Enable synchronous information output.

info-center synchronous

By default, synchronous information output is disabled.

Configuring log suppression

Enabling duplicate log suppression

About this task

The information center on the device outputs logs generated by service modules. The device identifies logs that have the same module name, level, mnemonic, location, and text as duplicate logs.

In some scenarios, for example, ARP attack or link failure, the service modules will generate a large volume of duplicate logs during a short period of time. Recording and output of consecutive duplicate logs wastes system and network resources. To resolve this issue, you can enable duplicate log suppression.

With this feature enabled, when a service module generates a log, the information center outputs the log and starts the duplicate log suppression timer. The suppression period of the duplicate log suppression timer varies by phase. The suppression periods in phase 1, 2, and later phases are 30 seconds, 2 minutes, and 10 minutes, respectively.

After you enable duplicate log suppression, the system starts suppression upon outputting a log:

- If only duplicate logs of the log are received during the suppression period of a phase, the information center does not output the duplicate logs. When the suppression period of the phase expires, the information center outputs the suppressed log and the number of times the log is suppressed, and starts the next suppression phase.
- If a different log is received during the suppression period of a phase, the information center performs the following operations:
  - Stops suppression on the log, and outputs the suppressed log and the number of times the log is suppressed.
  - Outputs the different log and starts phase-1 suppression for that log.
- If no log is received within the suppression period of any phase, the information center deletes the duplicate log suppression timer, stops suppression on the log, and does not output any log.

Procedure

1. Enter system view.

   system-view

2. Enable duplicate log suppression.

   info-center logging suppress duplicates

   By default, duplicate log suppression is disabled.

Examples

The following example uses SHELL_CMD logs to verify the duplicate log suppression feature. After the user executes a command on the device, the information center receives a SHELL_CMD log generated by the shell module, encapsulates the log, and then outputs the log to the log buffer.

1. Verify the suppression effect in phases 1, 2, 3, and 4 of a log (with suppression period of 30 seconds, 2 minutes, 10 minutes, and 10 minutes):

   # In a lab environment, continuously execute the **display logbuffer** command for 25 minutes.

   # View the output logs in the log buffer.

   ```
   <Sysname> display logbuffer
   ```

```
Log buffer: Enabled
Max buffer size: 1024
Actual buffer size: 512
Dropped messages: 0
Overwritten messages: 0
Current messages: 5
%Jul 20 13:01:20:615 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer
%Jul 20 13:01:50:718 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 2 times in last 30 seconds.
%Jul 20 13:03:50:732 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 5 times in last 2 minutes.
%Jul 20 13:13:50:830 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 10 times in last 10 minutes.
%Jul 20 13:23:50:211 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 6 times in last 10 minutes.
```

The output shows the following information:

- The information center received the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display logbuffer**.
- In phase 1, the log was suppressed twice by the information center.
- In phase 2, the log was suppressed five times by the information center.
- In phase 3, the log was suppressed 10 times by the information center.
- In phase 4, the log was suppressed six times by the information center.

2. Continue to verify how duplicate log suppression works when a different log is received during the suppression period of a log:

Execute the **`display logbuffer`** command three times, and then execute the **`display interface brief`** command.

View the output logs in the log buffer.

```
<Sysname> display logbuffer
Log buffer: Enabled
Max buffer size: 1024
Actual buffer size: 512
Dropped messages: 0
Overwritten messages: 0
Current messages: 5
%Jul 20 13:01:20:615 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer
%Jul 20 13:01:50:718 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 2 times in last 30 seconds.
%Jul 20 13:03:50:732 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 5 times in last 2 minutes.
%Jul 20 13:13:50:830 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 10 times in last 10 minutes.
%Jul 20 13:23:50:211 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 6 times in last 10 minutes.
%Jul 20 13:24:56:205 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 3 times in last 1 minute 6 seconds.
%Jul 20 13:25:41:205 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display interface brief.
<Sysname>
```

The output shows the following information:

- The information center stopped suppression for the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display logbuffer**.
- The information center output the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display interface brief**, and started suppression for it.

Configuring log suppression for a module

About this task

This feature suppresses output of logs. You can use this feature to filter out the logs that you are not concerned with.

Perform this task to configure a log suppression rule to suppress output of all logs or logs with a specific mnemonic value for a module.

Procedure

1. Enter system view.

   system-view

2. Configure a log suppression rule for a module.

   info-center logging suppress module *module-name* **mnemonic** { **all** | *mnemonic-value* }

   By default, the device does not suppress output of any logs from any modules.

Disabling an interface from generating link up or link down logs

About this task

By default, an interface generates link up or link down log information when the interface state changes. In some cases, you might want to disable certain interfaces from generating this information. For example:

- You are concerned about the states of only some interfaces. In this case, you can use this function to disable other interfaces from generating link up and link down log information.
- An interface is unstable and continuously outputs log information. In this case, you can disable the interface from generating link up and link down log information.

Use the default setting in normal cases to avoid affecting interface status monitoring.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Disable the interface from generating link up or link down logs.

   undo enable log updown

   By default, an interface generates link up and link down logs when the interface state changes.

Enabling SNMP notifications for system logs

About this task

This feature enables the device to send an SNMP notification for each log message it outputs. The device encapsulates the logs in SNMP notifications and then sends them to the SNMP module and the log trap buffer.

You can configure the SNMP module to send received SNMP notifications in SNMP traps or informs to remote hosts. For more information, see "Configuring SNMP."

To view the traps in the log trap buffer, access the MIB corresponding to the log trap buffer.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for system logs.
   snmp-agent trap enable syslog
   By default, the device does not send SNMP notifications for system logs.
3. Set the maximum number of traps that can be stored in the log trap buffer.
   info-center syslog trap buffersize *buffersize*
   By default, the log trap buffer can store a maximum of 1024 traps.

Managing security logs

Saving security logs to the security log file

About this task

Security logs are very important for locating and troubleshooting network problems. Generally, security logs are output together with other logs. It is difficult to identify security logs among all logs.

To solve this problem, you can save security logs to the security log file without affecting the current log output rules.

After you enable the security log file feature, the system processes security logs as follows:

1. Outputs security logs to the security log file buffer.
2. Saves logs from the security log file buffer to the security log file at the specified interval.
   If you have the security-audit role, you can also manually save security logs to the security log file.
3. Clears the security log file buffer immediately after the security logs are saved to the security log file.

Restrictions and guidelines

The device supports only one security log file. The system will overwrite old logs with new logs when the security log file is full. To avoid security log loss, you can set an alarm threshold for the security log file usage ratio. When the alarm threshold is reached, the system outputs a message to inform you of the alarm. You can log in to the device with the security-audit user role and back up the security log file to prevent the loss of important data.

Procedure

1. Enter system view.
   system-view

2. Enable the security log file feature.
   info-center security-logfile enable
   By default, the security log file feature is disabled.
3. Set the interval at which the system saves security logs.
   info-center security-logfile frequency *freq-sec*
   The default security log file saving interval is 86400 seconds.
4. (Optional.) Set the maximum size for the security log file.
   info-center security-logfile size-quota *size*
   By default, the maximum security log file size is 10 MB.
5. (Optional.) Set the alarm threshold of the security log file usage.
   info-center security-logfile alarm-threshold *usage*
   By default, the alarm threshold of the security log file usage ratio is 80. When the usage of the security log file reaches 80%, the system will send a message.

Managing the security log file

Restrictions and guidelines

To use the security log file management commands, you must have the security-audit user role. For information about configuring the security-audit user role, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Change the directory of the security log file.
   info-center security-logfile directory *dir-name*
   By default, the security log file is saved in the **seclog** directory in the root directory of the storage device.
   The device uses the default security log file directory after an IRF reboot or a master/subordinate switchover.
3. Manually save all logs in the security log file buffer to the security log file.
   security-logfile save
   This command is available in any view.
4. (Optional.) Display the summary of the security log file.
   display security-logfile summary
   This command is available in any view.

Saving diagnostic logs to the diagnostic log file

About this task

By default, the diagnostic log file feature saves diagnostic logs from the diagnostic log file buffer to the diagnostic log file at the specified saving interval. You can also manually trigger an immediate saving of diagnostic logs to the diagnostic log file. After saving diagnostic logs to the diagnostic log file, the system clears the diagnostic log file buffer.

The device supports only one diagnostic log file. The diagnostic log file has a maximum capacity. When the capacity is reached, the system replaces the oldest diagnostic logs with new logs.

Procedure

1. Enter system view.
   system-view
2. Enable the diagnostic log file feature.
   info-center diagnostic-logfile enable
   By default, the diagnostic log file feature is enabled.
3. (Optional.) Set the maximum diagnostic log file size.
   info-center diagnostic-logfile quota *size*
   By default, the maximum diagnostic log file size is 10 MB.
4. (Optional.) Specify the diagnostic log file directory.
   info-center diagnostic-logfile directory *dir-name*
   The default diagnostic log file directory is **flash:/diagfile**.
   The device uses the default diagnostic log file directory after an IRF reboot or a master/subordinate switchover.
5. Save diagnostic logs in the diagnostic log file buffer to the diagnostic log file. Choose one option as needed:
   - Configure the automatic diagnostic log file saving interval.
     info-center diagnostic-logfile frequency *freq-sec*
     The default saving interval is 86400 seconds.
   - Manually save diagnostic logs to the diagnostic log file.
     diagnostic-logfile save
     This command is available in any view.

Setting the maximum size of the trace log file

About this task

The device has only one trace log file. When the trace log file is full, the device overwrites the oldest trace logs with new ones.

Procedure

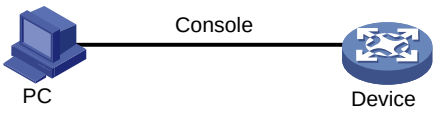
1. Enter system view.
   system-view
2. Set the maximum size for the trace log file.
   info-center trace-logfile quota *size*
   The default maximum size of the trace log file is 1 MB.

Display and maintenance commands for information center

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the diagnostic log file configuration.	**display diagnostic-logfile summary**

Task	Command
Display the information center configuration.	**display info-center**
Display information about log output filters.	**display info-center filter** [*filter-name*]
Display log buffer information and buffered logs.	**display logbuffer** [**reverse**] [**level** *severity* | **size** *buffersize* | **slot** *slot-number*] * [**last-mins** *mins*]
Display the log buffer summary.	**display logbuffer summary** [**level** *severity* | **slot** *slot-number*] *
Display the content of the log file buffer.	**display logfile buffer**
Display the log file configuration.	**display logfile summary**
Display the content of the security log file buffer. (To execute this command, you must have the security-audit user role.)	**display security-logfile buffer**
Display summary information of the security log file.	**display security-logfile summary**
Clear the log buffer.	**reset logbuffer**



Information center configuration examples

Example: Outputting logs to the console

Network configuration

Configure the device to output to the console FTP logs that have a minimum severity level of **warning**.

Figure 2 Network diagram

Procedure

Enable the information center.

```
<Device> system-view
[Device] info-center enable
```

Disable log output to the console.

```
[Device] info-center source default console deny
```

To avoid output of unnecessary information, disable all modules from outputting log information to the specified destination (**console** in this example) before you configure the output rule.

Configure an output rule to output to the console FTP logs that have a minimum severity level of **warning**.

```
[Device] info-center source ftp console level warning
[Device] quit
```

Enable log output to the console.

```
<Device> terminal logging level 6
<Device> terminal monitor
The current terminal is enabled to display logs.
```

Now, if the FTP module generates logs, the information center automatically sends the logs to the console, and the console displays the logs.

Example: Outputting logs to a UNIX log host

Network configuration

Configure the device to output to the UNIX log host FTP logs that have a minimum severity level of **informational**.

Figure 3 Network diagram

Procedure

1. Make sure the device and the log host can reach each other. (Details not shown.)
2. Configure the device:

   # Enable the information center.

   ```
   <Device> system-view
   [Device] info-center enable
   ```

   # Specify log host 1.2.0.1/16 with **local4** as the logging facility.

   ```
   [Device] info-center loghost 1.2.0.1 facility local4
   ```

   # Disable log output to the log host.

   ```
   [Device] info-center source default loghost deny
   ```

   To avoid output of unnecessary information, disable all modules from outputting logs to the specified destination (**loghost** in this example) before you configure an output rule.

   # Configure an output rule to output to the log host FTP logs that have a minimum severity level of **informational**.

   ```
   [Device] info-center source ftp loghost level informational
   ```

3. Configure the log host:

   The log host configuration procedure varies by the vendor of the UNIX operating system. The following shows an example:

   a. Log in to the log host as a root user.

   b. Create a subdirectory named **Device** in directory **/var/log/**, and then create file **info.log** in the **Device** directory to save logs from the device.

      ```
      # mkdir /var/log/Device
      # touch /var/log/Device/info.log
      ```

   c. Edit file **syslog.conf** in directory **/etc/** and add the following contents:

      ```
      # Device configuration messages
      local4.info /var/log/Device/info.log
      ```

      In this configuration, **local4** is the name of the logging facility that the log host uses to receive logs. The value **info** indicates the **informational** severity level. The UNIX system records the log information that has a minimum severity level of **informational** to file **/var/log/Device/info.log**.

NOTE:

Follow these guidelines while editing file **/etc/syslog.conf**:

- Comments must be on a separate line and must begin with a pound sign (#).
- No redundant spaces are allowed after the file name.
- The logging facility name and the severity level specified in the **/etc/syslog.conf** file must be identical to those configured on the device by using the **info-center loghost** and **info-center source** commands. Otherwise, the log information might not be output to the log host correctly.

d. Display the process ID of **syslogd**, kill the **syslogd** process, and then restart **syslogd** by using the **–r** option to validate the configuration.

```
# ps -ae | grep syslogd
147
# kill -HUP 147
# syslogd -r &
```

Now, the device can output FTP logs to the log host, which stores the logs to the specified file.

Example: Outputting logs to a Linux log host

Network configuration

Configure the device to output to the Linux log host 1.2.0.1/16 FTP logs that have a minimum severity level of **informational**.

Figure 4 Network diagram

Procedure

1. Make sure the device and the log host can reach each other. (Details not shown.)
2. Configure the device:

   # Enable the information center.

   ```
   <Device> system-view
   [Device] info-center enable
   ```

   # Specify log host 1.2.0.1/16 with **local5** as the logging facility.

   ```
   [Device] info-center loghost 1.2.0.1 facility local5
   ```

   # Disable log output to the log host.

   ```
   [Device] info-center source default loghost deny
   ```

   To avoid outputting unnecessary information, disable all modules from outputting log information to the specified destination (**loghost** in this example) before you configure an output rule.

   # Configure an output rule to enable output to the log host FTP logs that have a minimum severity level of **informational**.

   ```
   [Device] info-center source ftp loghost level informational
   ```

3. Configure the log host:

   The log host configuration procedure varies by the vendor of the Linux operating system. The following shows an example:

a. Log in to the log host as a root user.

b. Create a subdirectory named **Device** in directory **/var/log/**, and create file **info.log** in the **Device** directory to save logs from the device.

```
# mkdir /var/log/Device
# touch /var/log/Device/info.log
```

c. Edit file **syslog.conf** in directory **/etc/** and add the following contents:

```
# Device configuration messages
local5.info /var/log/Device/info.log
```

In this configuration, **local5** is the name of the logging facility that the log host uses to receive logs. The value **info** indicates the **informational** severity level. The Linux system will store the log information with a severity level equal to or higher than **informational** to file **/var/log/Device/info.log**.

NOTE:

Follow these guidelines while editing file **/etc/syslog.conf**:

- Comments must be on a separate line and must begin with a pound sign (#).
- No redundant spaces are allowed after the file name.
- The logging facility name and the severity level specified in the **/etc/syslog.conf** file must be identical to those configured on the device by using the **info-center loghost** and **info-center source** commands. Otherwise, the log information might not be output to the log host correctly.

d. Display the process ID of **syslogd**, kill the **syslogd** process, and then restart **syslogd** by using the **-r** option to validate the configuration.

Make sure the **syslogd** process is started with the **-r** option on the Linux log host.

```
# ps -ae | grep syslogd
147
# kill -9 147
# syslogd -r &
```

Now, the device can output FTP logs to the log host, which stores the logs to the specified file.

Configuring cloud connections

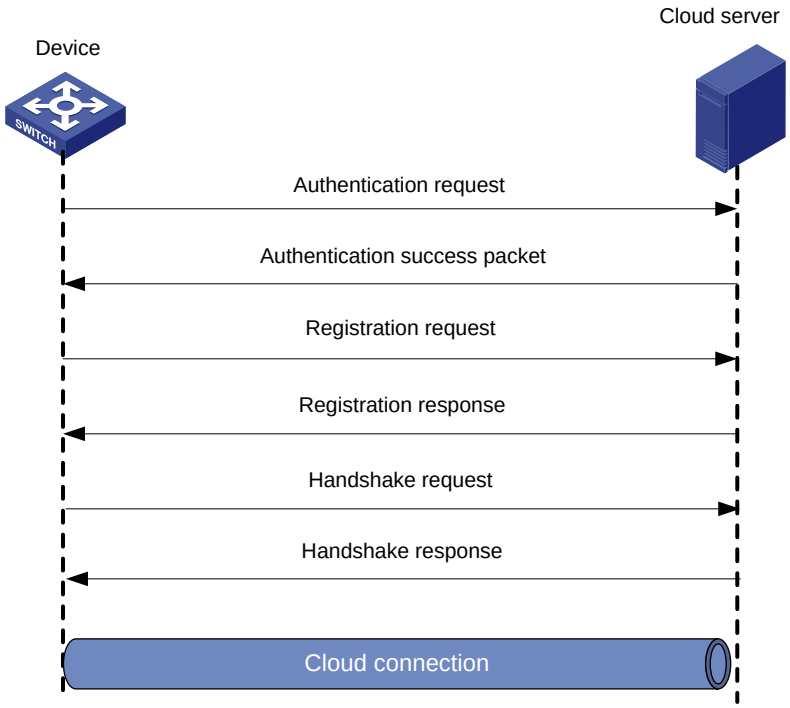
About cloud connections

A cloud connection is a management tunnel established between a local device and the H3C cloud server. It enables you to manage the local device from the cloud server without accessing the network where the device resides.

Multiple subconnections

After a local device establishes a connection with the cloud server, service modules on the local device can establish multiple subconnections with the microservices on the cloud server. These subconnections are independent from each other and provide separate communication channels for different services. This mechanism avoids interference among different services.

Cloud connection establishment



The cloud connection is established as follows:

1. The device sends an authentication request to the cloud server.
2. The cloud server sends an authentication success packet to the device.

   The device passes the authentication only if the serial number of the device has been added to the cloud server. If the authentication fails, the cloud server sends an authentication failure packet to the device.
3. The device sends a registration request to the cloud server.
4. The cloud server sends a registration response to the device.

   The registration response contains the uniform resource locator (URL) used to establish a cloud connection.
5. The device uses the URL to send a handshake request (changing the protocol from HTTP to WebSocket) to the cloud server.
6. The cloud server sends a handshake response to the device to finish establishing the cloud connection.
7. The device sends a subconnection URL request to the cloud server.
8. The cloud server sends a response that contains the microservice list and all subconnection URLs to the device.
9. The service module registers on the cloud connection management module.
10. The cloud connection management module sends the corresponding URLs to the service module.
11. The service module establishes subconnections with the cloud server.

Figure 1 Establishing a cloud connection

Configuring a cloud connection

About this task

For a device to establish a cloud connection to the cloud server, specify the domain name of the cloud server on the device.

For a device to establish a cloud connection to the cloud server, perform either of the following tasks:

- Specify the domain name of the cloud server on the device through CLI.
- Configure an interface of the device as a DHCP client and the cloud server as the DHCP server. The device obtains the IP address of the DHCP server and parses the option 253 field in the DHCP packets to obtain the IPv4 domain name of the cloud server. It parses the option 65253 field in the DHCPv6 packets to obtain the IPv6 domain name of the cloud server. For more information about the option 253 field and the option 65253 field, see DHCP configuration and DHCPv6 configuration in *Layer 3—IP Services Configuration Guide*.

After establishing the cloud connection, the local device sends keepalive packets to the cloud server periodically. If the device does not receive a response from the cloud server within three keepalive intervals, the device sends a registration request to re-establish the cloud connection.

Prerequisites

Add the serial number of the device to be managed to the cloud server.

Configure DNS to ensure that the domain name of the cloud server can be translated into an IP address.

Restrictions and guidelines

The domain name obtained through DHCP has a higher priority than the domain name configured manually.

If a device obtains the domain name of the cloud server through DHCP after establishing a cloud connection to the cloud server with the manually configured domain name, the device performs the following tasks:

- If the automatically obtained and manually configured domain names are identical, the device retains the cloud connection.
- If the automatically obtained and manually configured domain names are different, the device tears down the cloud connection and then establishes a cloud connection to the cloud server with the automatically obtained domain name.

Procedure

1. Enter system view.

   system-view

2. Configure the domain name of the cloud server.
   - Configure the IPv4 domain name of the cloud server.

     cloud-management server { **domain** *domain-name* [**vpn-instance** *vpn-instance-name*] [**source-ip** *ip-address*] | **port** *port-number* }
   - Configure the IPv6 domain name of the cloud server.

     cloud-management server ipv6 domain *domain-name* [**vpn-instance** *vpn-instance-name*] [**source-ip** *ip-address*]

   By default:
   - In a version earlier than F1127, the domain name of the cloud server is not configured.
   - In F1127 or a later version, when the device starts up without loading any configuration, the domain name of the cloud server is not configured. If the device starts up with the factory settings, the domain name of the cloud server is cloudnet.h3c.com.

   Only the R1122 and later versions support configuring the IPv6 domain name of the cloud server.
3. (Optional) Set the keepalive interval.

   cloud-management keepalive *interval*

   By default, the keepalive interval is 180 seconds.
4. (Optional) Specify the TCP port number used to establish cloud connections.

   cloud-management server port *port-number*

   By default, the TCP port number used to establish cloud connections is 443.
5. (Optional.) Set the password for establishing cloud connections to the cloud server.

   cloud-management server password { **cipher** | **simple** } *string*

   By default, no password is set for establishing cloud connections to the cloud server.

   The feature is supported only in R1107 and later.

Unbinding the device from the Oasis server

About this task

A device can be registered on the Oasis server by only one user.

To register a device that has been registered by another user, you need to take the following steps:

1. Obtain a verification code for device unbinding from the Oasis server.
2. Execute the command on the device for sending the verification code to the Oasis server.
3. Register the device on the Oasis server.

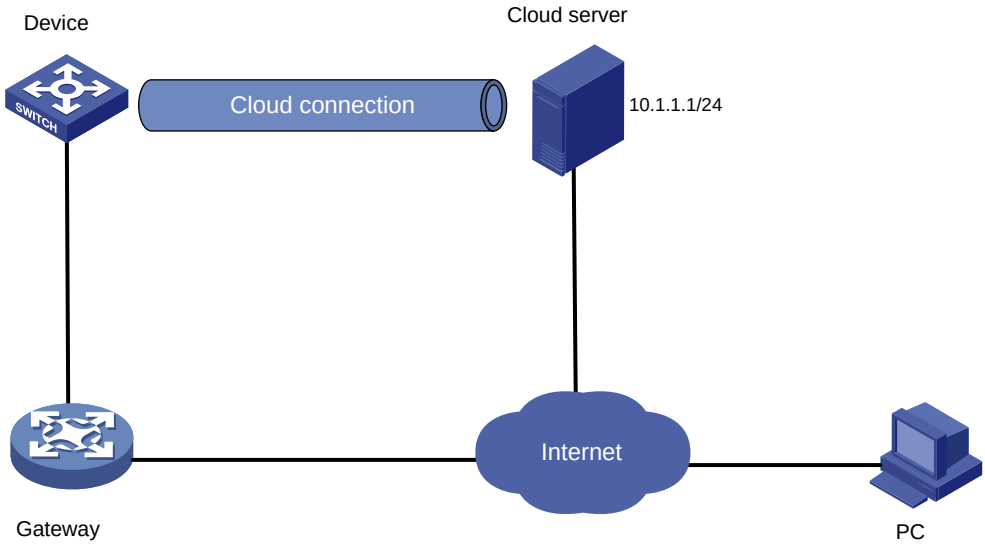
Procedure

1. Enter system view.
   system-view
2. Send the verification code for device unbinding to the Oasis server.
   cloud-management unbinding-code *code*

Display and maintenance commands for cloud connections

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display cloud connection state information.	**display cloud-management state**
Re-establish the cloud connection to the cloud server.	**reset cloud-management tunnel**



Cloud connection configuration examples

Example: Configuring a cloud connection

Network configuration

As shown in Figure 2, configure the device to establish a cloud connection with the cloud server.

Figure 2 Network diagram

Procedure

1. Configure IP addresses for interfaces, and configure a routing protocol to ensure that the devices can reach each other. (Details not shown.)
2. Log in to the cloud server to add the serial number of the device to the server. (Details not shown.)

The IP address of the cloud server is 10.1.1.1/24 and the domain name is **cloud.com**.

3. Configure the domain name of the cloud server as **cloud.com**.

```
<Device> system-view
[Device] cloud-management server domain cloud.com
```

Map IP address 10.1.1.1 to host name **cloud.com**.

```
[Device] ip host cloud.com 10.1.1.1
```

Verifying the configuration

Verify that the device and the cloud server have established a cloud connection.

```
[Device] display cloud-management state
Cloud connection state   : Established
Device state             : Request_success
Cloud server address     : 10.1.1.1
Cloud server domain name : cloud.com
Cloud server port        : 443
Connected at             : Wed Jan  27 14:18:40 2019
Duration                 : 00d 00h 02m 01s
```

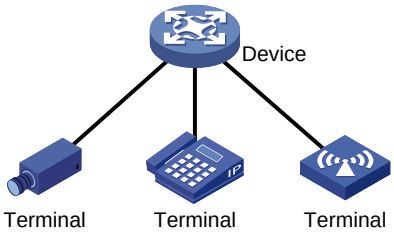
Configuring EPA

About EPA



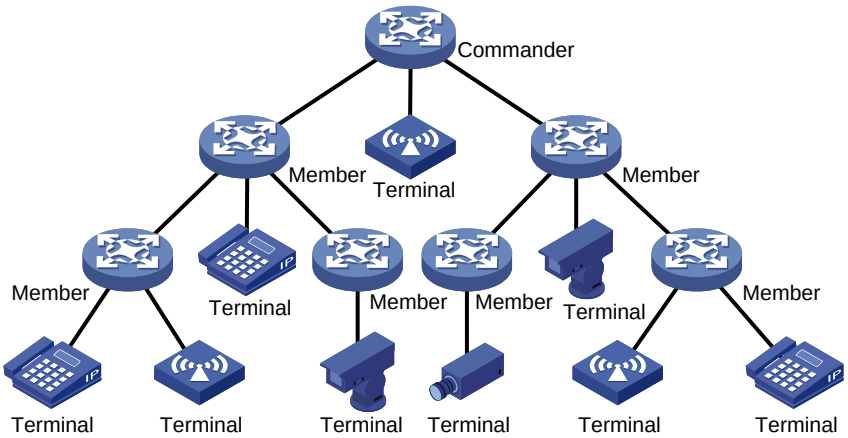
Endpoint Analysis (EPA) allows you to monitor associations and disassociations of endpoints (for example, cameras and IP phones) connecting to an H3C device.

Application scenarios

Non-SmartMC networking

As shown in Figure 1, the device configured with EPA monitors associations and disassociations of endpoints connecting to it. The device can be a standalone device or an IRF fabric. For an IRF fabric, EPA monitors endpoints connecting to all members. The collected association and disassociation information will be reported to the master device for processing.

Figure 1 Non-SmartMC networking



SmartMC networking

In a SmartMC network as shown in Figure 2, EPA settings are configured only on the commander. The members report association and disassociation information about their associated endpoints to the commander. The commander records such information about all associated endpoints in the network, and deploys EPA settings to the members.

You can view EPA information in the entire network on the commander.

Figure 2 SmartMC networking

Endpoint identification methods

EPA supports the following endpoint identification methods:

- **Static identification**—Identifies associations and disassociations of endpoints by matching MAC addresses of the endpoints. This method requires manual configuration of endpoint MAC addresses on the device and is applicable to networks with a small number of endpoints. This method can only identify cameras and cannot identify the vendor and operating system of cameras.
- **Automatic identification**—Identifies associations and disassociations of endpoints through the fields in packets. This method is applicable to networks with a large number of endpoints. This method can identify the endpoint category, vendor and operating system of endpoints. This method needs to work with BYOD.

Static endpoint identification

EPA monitors endpoint associations and disassociations by monitoring the generation and aging of MAC address entries learned by devices. A device configured with EPA can monitor only endpoints in the same subnet as the endpoint access port on the device.

For more information about MAC address entries, see *Layer 2—LAN Switching Configuration Guide*.

Collecting endpoint association information

If a device configured with EPA learns a new MAC address entry, it compares the MAC address and VLAN ID with the configured EPA monitor rules.

- If a match is found, the device determines that a monitored endpoint came online.
  - In a non-SmartMC network, the device records the endpoint association event locally.
  - In a SmartMC network, if the device is the commander, it records the endpoint association event locally. If the device is a member, it reports the event to the commander.
- If no match is found, the device determines that the endpoint is not a monitored endpoint and does not record the endpoint association event.

Collecting endpoint disassociation information

When the MAC address entry of an endpoint ages out, the device determines that the endpoint went offline.

- In a non-SmartMC network, the device records the endpoint disassociation event locally for 7 days.
- In a SmartMC network, the commander records the endpoint disassociation event for 7 days.

Synchronizing information in a SmartMC network

In a SmartMC network, endpoint monitor rules are configured on the commander and deployed to all members by the commander. The rules take effect on both the commander and members. If a member detects an association or disassociation event of a monitored endpoint, it reports the event to the commander for statistics collection and analysis.

You can view endpoint associations and disassociations that occurred in the entire network from the commander. For more information about SmartMC, see "Configuring SmartMC."

Automatic endpoint identification

As Internet technologies develop, many enterprises allow employees to use their own mobile devices (for example, mobile phones, tablets, and laptops) to access internal networks. This might create security risks. To ensure security by managing endpoints, administrators must know what endpoints are in the network, including endpoint category and endpoint operating system.

EPA can automatically identify endpoints by working with BYOD. When an endpoint accesses the network, EPA obtains fingerprint information from the authentication request of an endpoint and matches the fingerprint with the BYOD endpoint identification rules. If a match is found, EPA considers that the endpoint is online and records the MAC address, endpoint category, and vendor of the endpoint.

A BYOD endpoint identification rule is a fingerprint entry, which includes the fingerprint type, fingerprint value, endpoint category, and endpoint vendor, and endpoint OS.

BYOD supports the following endpoint fingerprints:

- **DHCP Option 55 fingerprint**—Parameter request list option. The option is used by an endpoint to request specified configuration parameters. To use this fingerprint, enable recording of client information in DHCP snooping entries on the access interface of endpoints. For more information about DHCP Option55 and DHCP snooping, see DHCP in *Layer 3—IP Services Configuration Guide*.
- **HTTP user agent fingerprint**—Located in the header of HTTP requests to carry information about the endpoint operating system, Web browser, and versions. To use this fingerprint, enable portal authentication on the access interface of endpoints. For more information about portal authentication, see DHCP in *Security Configuration Guide*.
- **MAC address fingerprint**—MAC address of the endpoint or MAC address range to which the endpoint belongs.

Static endpoint identification has higher priority than dynamic endpoint identification. The device matches fingerprint information for an endpoint in the following order:

1. DHCP Option 55 fingerprint.
2. HTTP user agent fingerprint.
3. MAC address fingerprint.

The system has predefined BYOD endpoint identification rules. You can also configure BYOD endpoint identification rules depending on the network requirements.

For more information about BYOD, see AAA in *Security Configuration Guide*.

Restrictions: Software compatibility with EPA

Only software versions of Release 1112 and later support the EPA feature.

Restrictions and guidelines: EPA configuration

Do not use the **mac-address dynamic** command to configure dynamic MAC address entries for monitored endpoints. If you do so, the system might fail to identify endpoint association events.

When you configure EPA in a SmartMC network, follow these restrictions and guidelines:

- Make sure all devices in the network support EPA.
- You can configure endpoint monitor rules only on the commander.
- Configure the same aging time for MAC address entries on all devices in the SmartMC network. Otherwise, endpoint association and disassociation analysis on the commander might be inaccurate. For more information about MAC address entries, see *Layer 2—LAN Switching Configuration Guide*.
- To view endpoint association and disassociation events in a SmartMC network, execute the **display epa monitor-information** command on the commander instead of a member. If you execute the command on a member, the command displays only association events of endpoints connecting to the member.

Configuring static endpoint identification

Restrictions and guidelines

When you configure static endpoint identification rules, follow these restrictions and guidelines:

- To configure multiple rules to monitor an endpoint in different VLANs, make sure the specified VLAN ranges in these rules do not overlap with each other.
- As a best practice to ensure the optimal EPA performance, specify the VLANs in which an endpoint will be monitored.
- If you configure a rule to monitor an endpoint in all VLANs, make sure the endpoint will not come online from over 10 VLANs.
- You can configure a maximum of 1024 monitor rules. As a best practice to ensure the optimal EPA performance, do not configure over 512 monitor rules.
- You can specify a rule ID when creating a monitor rule. If you do not specify the ID, the system assigns the smallest available ID to the rule.
- You cannot execute the **epa monitor-rule** command multiple times to edit an existing rule. To edit an existing rule, use the **undo epa monitor-rule** command to delete the rule and then create the rule again.

Procedure

1. Enter system view.

   system-view

2. Create a static endpoint identification rule.

   epa monitor-rule [*monitor-rule-id*] **mac** *mac-address* [**mask** *mac-mask*] [**vlan** *vlan-id*]

   By default, no static endpoint identification rules exist.

Configuring dynamic endpoint identification

Prerequisites

The system has predefined BYOD endpoint identification rules. You can also configure BYOD endpoint identification rules depending on the network requirements (see AAA in *Security Configuration Guide*).

Restrictions and guidelines

After you modify a fingerprint entry, the modified parameters are reflected for matching online endpoints only if they log out and log in again.

Procedure

1. Enter system view.

   system-view

2. Enable automatic endpoint identification.

   epa auto-identify enable

   By default, automatic endpoint identification is disabled.

Disabling EPA logging

About this task

By default, the EPA module logs endpoint associations and disassociations. If a monitored endpoint comes online or goes offline frequently, the device will generate a large number of log entries. In this case, to avoid affecting device performance, disable EPA logging as a best practice.

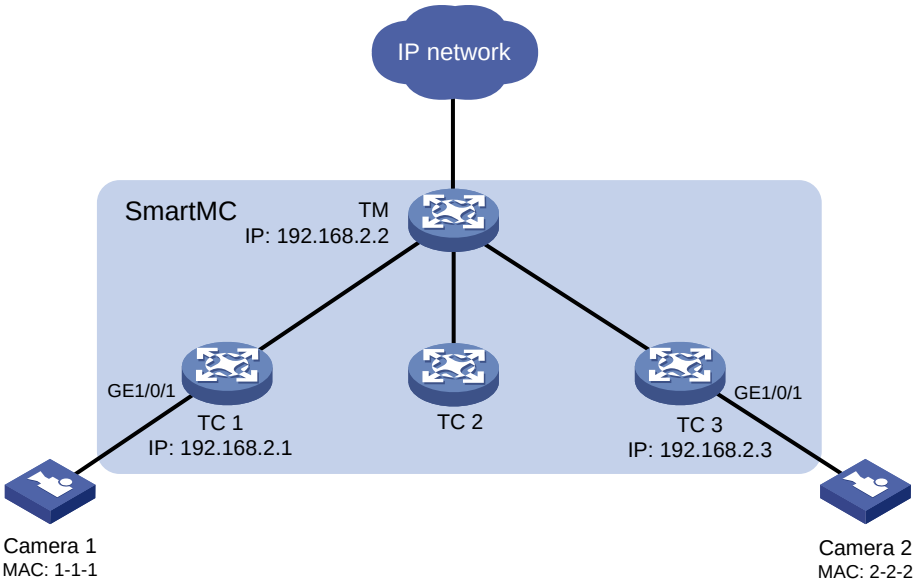
Procedure

1. Enter system view.
   `system-view`
2. Disable EPA logging.
   `epa online-offline-log disable`
   By default, EPA logging is enabled.

Display and maintenance commands for EPA

Execute **`display`** commands in any view.

Task	Command
Display endpoint association and disassociation information detected by EPA.	**`display epa monitor-information`** [**`online`** | **`offline`**] [**`device`** *`device-id`* | **`mac`** *`mac-address`* [**`vlan`** *`vlan-id`*]] [**`verbose`**]



EPA configuration examples

Example: Configuring static endpoint identification

Network configuration

As shown in Figure 3, the SmartMC network is established manually. Configure the devices in SmartMC network so EPA can automatically identify camera 1 and camera 2 when they access the SmartMC network.

Figure 3 Network diagram

Configuring the TM

1. Configure SmartMC:

Configure VLAN-interface 1.

```
[TM] interface vlan-interface 1
[TM-Vlan-interface1] ip address 192.168.2.2 24
[TM-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TM] ip http enable
[TM] ip https enable
```

Enable the Telnet service.

```
[TM] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

2. Configure static endpoint identification rules on the commander.

```
[TM] epa monitor-rule mac 1-1-1
[TM] epa monitor-rule mac 2-2-2
```

Configuring TC 1

1. Configure SmartMC:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.1 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user named **admin**.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

Configuring TC 3

Configure TC 3 in the same way TC 1 is configured. (Details not shown.)

Verifying the configuration

On TC 1, display the online and offline information of endpoints.

```
[TC1] display epa monitor-information verbose
Auto identification : Disabled
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
```

```
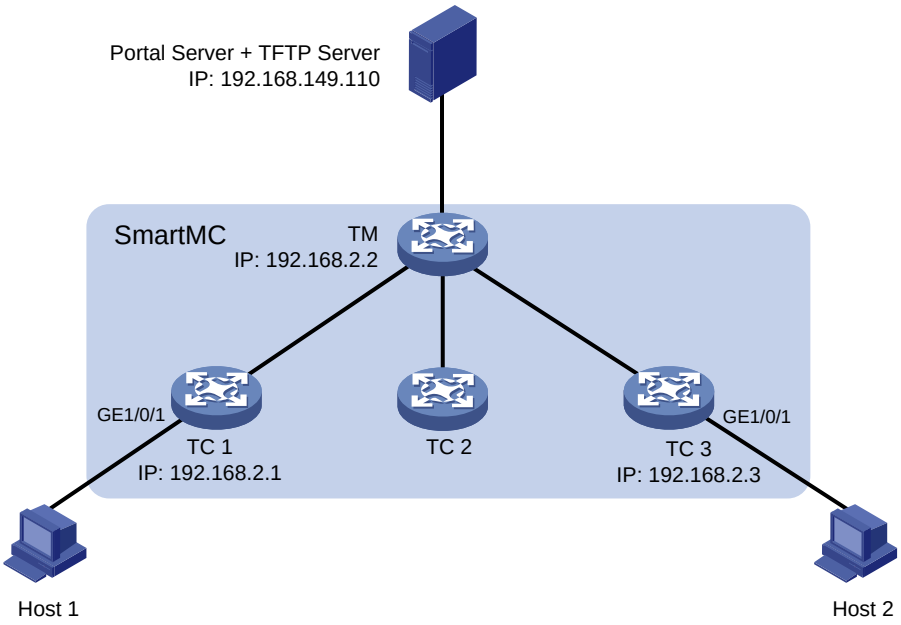
Total endpoints identified by EPA: 1

Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : 1
  IP address    : -
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : Camera                   Vendor: -
  OS            : -
```

On the TM, display the online and offline information of endpoints.

```
[TM] display epa monitor-information verbose
Auto identification : Disabled
Local device type   : SmartMC TM
Local device ID     : 90bc-1b85-0300
Total endpoints identified by EPA: 2

Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : 1
  IP address    : 192.168.2.11
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : Camera                   Vendor: -
  OS            : -



Access device ID: 3acc-58e2-0300
  MAC address   : 0002-0002-0002           VLAN  : 1
  IP address    : 192.168.2.12
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : Camera                   Vendor: -
  OS            : -
```

Example: Configuring automatic endpoint identification (portal authentication)

Network configuration

As shown in Figure 4, the SmartMC network is established automatically. Configure the devices in SmartMC network so EPA can automatically identify host 1 and host 2 when they access the SmartMC network through portal authentication.

Figure 4 Network diagram

Configuring the TM

1. Configure SmartMC:

Configure VLAN-interface 1.

```
[TM] interface vlan-interface 1
[TM-Vlan-interface1] ip address 192.168.2.1 24
[TM-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TM] ip http enable
[TM] ip https enable
```

Enable the Telnet service.

```
[TM] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

2. Enable EPA automatic endpoint identification on the commander.

```
[TM] epa auto-identify enable
```

Configuring TC 1

1. Configure SmartMC:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.2 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user named **admin**.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

2. Configure portal authentication:

Create an ISP domain named **dm1** and enter its view.

```
[TC1] domain dm1
```

Configure AAA methods for the ISP domain.

```
[TC1-isp-dm1] authentication portal local
[TC1-isp-dm1] authorization portal local
[TC1-isp-dm1] accounting portal local
[TC1-isp-dm1] quit
```

Configure a portal Web server.

```
[TC1] portal web-server newpt
[TC1-portal-websvr-newpt] url http://192.168.149.110:2331/portal
[TC1-portal-websvr-newpt] quit
```

Enable direct portal authentication on GigabitEthernet 1/0/1.

```
[TC1] interface gigabitethernet 1/0/1
[TC1-GigabitEthernet1/0/1] port link-mode route
[TC1-GigabitEthernet1/0/1] ip address 192.168.149.110 16
[TC1-GigabitEthernet1/0/1] portal enable method direct
```

Specify portal Web server **newpt** on GigabitEthernet 1/0/1.

```
[TC1-GigabitEthernet1/0/1] portal apply web-server newpt
[TC1-GigabitEthernet1/0/1] quit
[TC1] quit
```

Download an authentication page file from a TFTP server.

```
<TC1> tftp 192.168.149.110 get defaultfile.zip
```

Create an HTTP-based local portal Web service and enter its view.

```
<TC1> system-view
[TC1] portal local-web-server http
```

Specify file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the file exist under the root directory of the router.)

```
[TC1-portal-local-websvr-http] default-logon-page defaultfile.zip
```

Set the HTTP listening port number to 2331 for the local portal Web service.

```
[TC1-portal-local-websvr-http] tcp-port 2331
[TC1-portal-local-websvr-http] quit
```

3. Configure a BYOD endpoint identification rule:

Configure a rule to identify BYOD endpoints containing HTTP UserAgent fingerprint **Mozilla/5.0**.

```
[TC1] byod rule http-user-agent Mozilla/5.0 device-attributes
```

Configure at least one piece of the following fingerprint information.

```
[TC1-byod-ua-Mozilla/5.0] device-category PC
[TC1-byod-ua-Mozilla/5.0] device-vendor Xerox
[TC1-byod-ua-Mozilla/5.0] device-os "Window Vista/7 or Server 2008 (Version 6.0)"
[TC1-byod-ua-Mozilla/5.0] quit
```

Configuring TC 3

Configure TC 3 in the same way TC 1 is configured. (Details not shown.)

Verifying the configuration

On TC 1, verify that EPA can successfully identify the hosts when they come online.

```
[TC1] display epa monitor-information verbose
Auto identification : Enabled
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Total endpoints identified by EPA: 1
Access device ID: 3acc-58e2-0100
  MAC address   : 0a00-2700-0010           VLAN  : -
  IP address    : 192.168.226.1
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
```

```
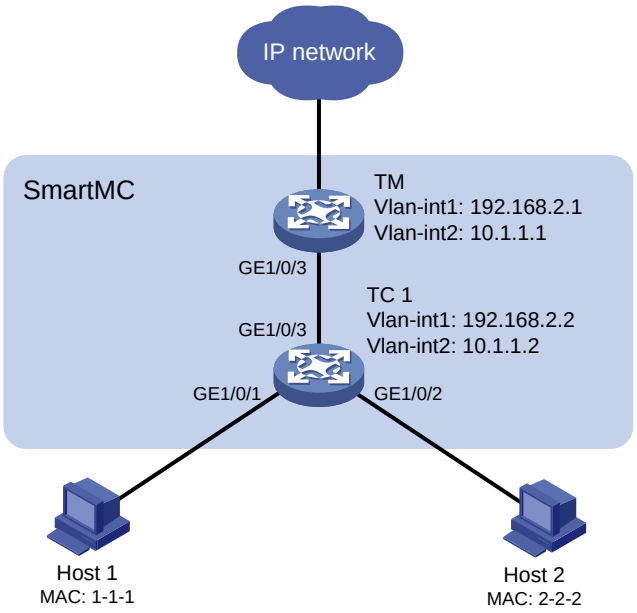
  OS           : Windows Vista/7 or Server 2008 (Version 6.0)
```

On the TM, verify that EPA can successfully identify the hosts when they come online.

```
[TM] display epa monitor-information verbose
Auto identification : Enabled
Local device type    : SmartMC TM
Local device ID      : 90bc-1b85-0300
Total endpoints identified by EPA: 2

Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : -
  IP address    : 192.168.226.1
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Windows Vista/7 or Server 2008 (Version 6.0)



Access device ID: 3acc-58e2-0300
  MAC address   : 0002-0002-0002           VLAN  : -
  IP address    : 192.168.226.2
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Windows Vista/7 or Server 2008 (Version 6.0)
```

Example: Configuring automatic endpoint identification (DHCP)

Network configuration

As shown in Figure 5, the SmartMC network is established automatically. Configure the devices in SmartMC network so EPA can automatically identify host 1 and host 2 when they access the SmartMC network through DHCP.

Figure 5 Network diagram

Configuring the TM

1. Configure SmartMC:

   # Configure VLAN-interface 1.

   ```
   [TM] interface vlan-interface 1
   [TM-Vlan-interface1] ip address 192.168.2.1 24
   [TM-Vlan-interface1] quit
   ```

   # Enable HTTP and HTTPS.

   ```
   [TM] ip http enable
   [TM] ip https enable
   ```

   # Enable the Telnet service.

   ```
   [TM] telnet server enable
   ```

   # Enable NETCONF over SOAP over HTTP.

   ```
   [TM] netconf soap http enable
   ```

   # Enable LLDP globally.

   ```
   [TM] lldp global enable
   ```

   # Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

   ```
   [TM] local-user admin
   [TM-luser-manage-admin] password simple hello12345
   [TM-luser-manage-admin] service-type telnet http https
   [TM-luser-manage-admin] authorization-attribute user-role network-admin
   [TM-luser-manage-admin] quit
   ```

   # Set scheme authentication for VTY user lines 0 to 63.

   ```
   [TM] line vty 0 63
   [TM-line-vty0-63] authentication-mode scheme
   [TM-line-vty0-63] quit
   ```

   # Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

   ```
   [TM] smartmc tm username admin password simple hello12345 enable
   ```

2. Configure the DHCP server:

   # Configure VLAN-interface 2.

   ```
   <TM> system-view
   [TM] vlan 2
   [TM-vlan2] quit
   [TM] interface vlan-interface 2
   [TM-Vlan-interface2] ip address 10.1.1.1 24
   [TM-Vlan-interface2] quit
   ```

   # Exclude the IP address of the DNS server from dynamic allocation.

   ```
   [TM] dhcp server forbidden-ip 10.1.1.2
   ```

   # Configure DHCP address pool 0 to assign IP addresses and other configuration parameters to clients on subnet 10.1.1.0/24.

   ```
   [TM] dhcp server ip-pool 0
   [TM-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
   [TM-dhcp-pool-0] expired day 10
   [TM-dhcp-pool-0] quit
   ```

   # Enable DHCP.

   ```
   [RouterA] dhcp enable
   ```

3. Enable EPA automatic endpoint identification on the commander.

```
[TM] epa auto-identify enable
```

4. Configure GigabitEthernet 1/0/3.

```
[TM] interface gigabitethernet 1/0/3
[TM-GigabitEthernet1/0/3] port link-type trunk
[TM-GigabitEthernet1/0/3] port trunk permit vlan all
```

Configuring TC 1

1. Configure SmartMC:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.2 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user named **admin**.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

2. Configure DHCP snooping:

Enable DHCP snooping globally.

```
<TC1> system-view
[TC1] dhcp snooping enable
```

Assign an IP address to VLAN-interface 2.

```
[TC1] vlan 2
```

```
[TC1-vlan2] quit
[TC1] interface vlan-interface 2
[TC1-Vlan-interface2] ip address 10.1.1.2 24
[TC1-Vlan-interface2] quit
```

Assign GigabitEthernet 1/0/1 to VLAN 2, and configure it as a trusted port.

```
[TC1] interface gigabitethernet 1/0/1
[TC1-GigabitEthernet1/0/1] port access vlan 2
[TC1-GigabitEthernet1/0/1] dhcp snooping trust
[TC1-GigabitEthernet1/0/1] quit
```

Assign GigabitEthernet 1/0/2 to VLAN 2, and configure it as a trusted port.

```
[TC1] interface gigabitethernet 1/0/2
[TC1-GigabitEthernet1/0/2] port access vlan 2
[TC1-GigabitEthernet1/0/2] dhcp snooping trust
[TC1-GigabitEthernet1/0/2] quit
```

3. Configure GigabitEthernet 1/0/3.

```
[TC1] interface gigabitethernet 1/0/3
[TC1-GigabitEthernet1/0/3] port link-type trunk
[TC1-GigabitEthernet1/0/3] port trunk permit vlan all
```

4. Configure a BYOD endpoint identification rule:

If you use the default fingerprint information, skip this step.

Configure a rule to identify BYOD endpoints containing DHCP Option55 fingerprint **1,121,3,6,12,15,33,43,66,67,138,150**.

```
[TC1] byod rule dhcp-option 1,121,3,6,12,15,33,43,66,67,138,150 device-attribute
```

Configure at least one piece of the following fingerprint information.

```
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-category PC
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-vendor Xerox
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-os "Window Vista/7 or
Server 2008 (Version 6.0)"
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] quit
```

5. Configure host 1 and host 2 to obtain IP addresses through DHCP.

Verifying the configuration

On TC 1, verify that EPA can successfully identify the hosts when they come online.

```
[TC1] display epa monitor-information verbose
Auto identification : Enabled
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Total endpoints identified by EPA: 2

Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : 2
  IP address    : 10.1.1.3
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)

Access device ID: 3acc-58e2-0100
  MAC address   : 0002-0002-0002           VLAN  : 2
```

```
  IP address    : 10.1.1.4
  Interface     : GigabitEthernet1/0/2      Status: Online
  Category      : PC                        Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)
```

On the TM, verify that EPA can successfully identify the hosts when they come online.

```
[TM] display epa monitor-information verbose
Auto identification : Enabled
Local device type    : SmartMC TM
Local device ID     : 90bc-1b85-0300
Total endpoints identified by EPA: 2

Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001            VLAN  : 2
  IP address    : 10.1.1.3
  Interface     : GigabitEthernet1/0/1      Status: Online
  Category      : PC                        Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)

Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001            VLAN  : 2
  IP address    : 10.1.1.4
  Interface     : GigabitEthernet1/0/2      Status: Online
  Category      : PC                        Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)

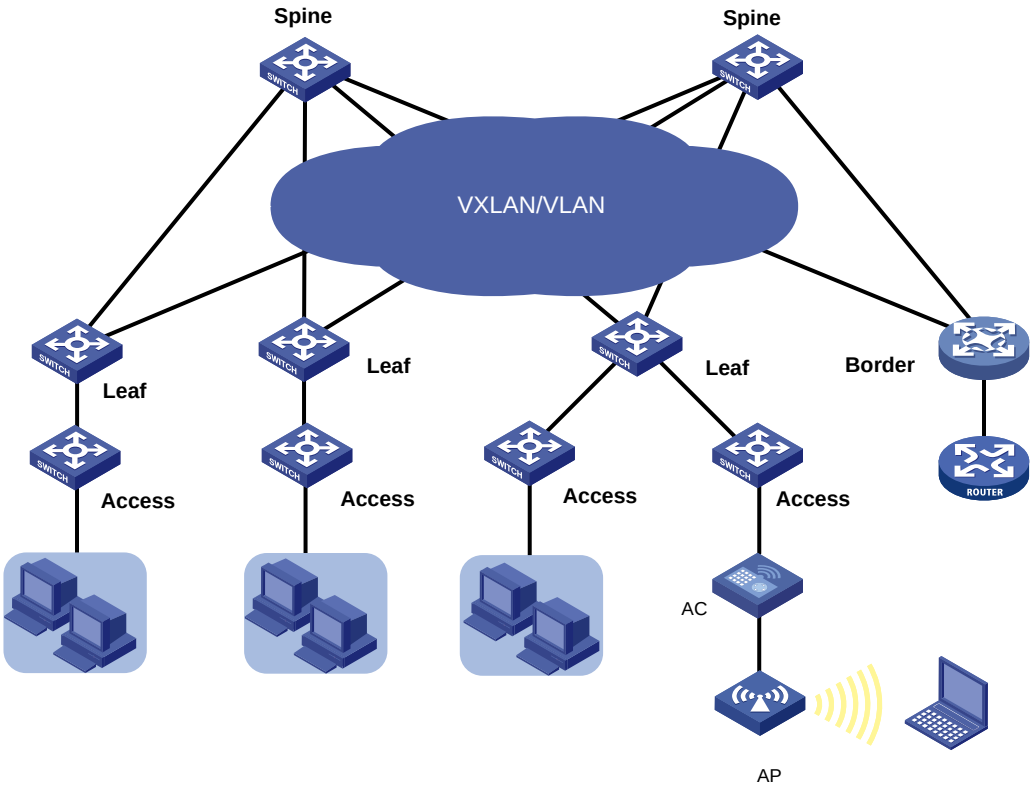
Configuring VCF fabric

About VCF fabric

Based on OpenStack Networking (Neutron), the Virtual Converged Framework (VCF) solution provides virtual network services from Layer 2 to Layer 7 for cloud tenants. This solution breaks the boundaries between the network, cloud management, and terminal platforms and transforms the IT infrastructure to a converged framework to accommodate all applications. It also implements automated topology discovery and automated deployment of underlay networks and overlay networks to reduce the administrators' workload and speed up network deployment and upgrade.

VCF fabric topology

VCF fabric topology for a campus network



In a campus VCF fabric, a device has one of the following roles:

- **Spine node**—Connects to leaf nodes.
- **Leaf node**—Connects to access nodes.
- **Access node**—Connects to an upstream leaf node and downstream terminal devices. Cascading of access nodes is supported.
- **Border node**—Located at the border of a VCF fabric to provide access to the external network.

Spine nodes and leaf nodes form a large Layer 2 network.

The switch series can be used only as access nodes.

Figure 1 VCF fabric topology for a campus network

Automated VCF fabric deployment

VCF provides the following features to ease deployment:

- Automated topology discovery.

  In a VCF fabric, each device uses LLDP to collect local topology information from directly-connected peer devices. The local topology information includes connection interfaces, roles, MAC addresses, and management interface addresses of the peer devices. If multiple spine nodes exist in a VCF fabric, the master spine node collects the topology for the entire network.

- Automated underlay network deployment.

  Automated underlay network deployment sets up a Layer 3 underlay network (a physical Layer 3 network) for users. It is implemented by automatically executing configurations (such as IRF configuration and Layer 3 reachability configurations) in user-defined template files.

Process of automated VCF fabric deployment

The device finishes automated VCF fabric deployment as follows:

1. Starts up without loading configuration and then obtains an IP address, the IP address of the TFTP server, and a template file name from the DHCP server.
2. Determines the name of the template file to be downloaded based on the device role and the template file name obtained from the DHCP server. For example, 1_leaf**.template** represents a template file for leaf nodes.
3. Downloads the template file from the TFTP server.
4. Parses the template file and performs the following operations:

- Deploys static configurations that are independent from the VCF fabric topology.
- Deploys dynamic configurations according to the VCF fabric topology.

  The topology process notifies the automation process of creation, deletion, and status change of neighbors. Based on the topology information, the automation process completes role discovery, automatic aggregation, and IRF fabric setup.

Template file

A template file contains the following contents:

- **System-predefined variables**—The variable names cannot be edited, and the variable values are set by the VCF topology discovery feature.
- **User-defined variables**—The variable names and values are defined by the user. These variables include the username and password used to establish a connection with the Neutron server, network type, and so on. The following are examples of user-defined variables:

  ```
  #USERDEF
  _username = aaa
  _password = hello12345
  _rbacUserRole = network-admin
  _loghost_ip = 172.16.1.136
  …
  ```
- **Static configurations**—Static configurations are independent from the VCF fabric topology and can be directly executed. The following are examples of static configurations:

  ```
  #STATICCFG
  #
   clock timezone beijing add 08:00:00
  #
   lldp global enable
  #
   stp global enable
  #
  ```
- **Dynamic configurations**—Dynamic configurations are dependent on the VCF fabric topology. The device first obtains the topology information through LLDP and then executes dynamic configurations. The following are examples of dynamic configurations:

  ```
  #
  interface $$_underlayIntfDown
   port link-mode route
   ip address unnumbered interface LoopBack0
   ospf 1 area 0.0.0.0
   ospf network-type p2p
   lldp management-address arp-learning
   lldp tlv-enable basic-tlv management-address-tlv interface LoopBack0
  #
  ```

VCF fabric task at a glance

To configure a VCF fabric, perform the following tasks:

- Configuring automated VCF fabric deployment

  No tasks are required to be made on the device for automated VCF fabric deployment. However, you must make related configuration on the DHCP server and the TFTP server so

the device can download and parse a template file to complete automated VCF fabric deployment.

- (Optional.) Adjust VCF fabric deployment

  If the device cannot obtain or parse the template file to complete automated VCF fabric deployment, choose the following tasks as needed:

  - Enabling VCF fabric topology discovery
  - Configuring automated underlay network deployment

Configuring automated VCF fabric deployment

Restrictions and guidelines

The default role of the switch in the VCF fabric of a campus network is an access node. You cannot change its role.

On a campus network, links between two access nodes cascaded through GigabitEthernet interfaces and links between leaf nodes and access nodes are automatically aggregated. For links between spine nodes and leaf nodes, the **`trunk permit vlan`** command is automatically executed.

On a campus network where multiple leaf nodes that have an access node attached form an IRF fabric, make sure only one link exists between each leaf node and its connected access node.

Do not perform link migration when devices in the VCF fabric are in the process of coming online or powering down after the automated VCF fabric deployment finishes. A violation might cause link-related configuration fails to update.

The version format of a template file for automated VCF fabric deployment is *x*.*y*. Only the *x* part is examined during a version compatibility check. For successful automated deployment, make sure *x* in the version of the template file to be used is not greater than *x* in the supported version. To display the supported version of the template file for automated VCF fabric deployment, use the **`display vcf-fabric underlay template-version`** command.

If the template file does not include IRF configurations, the device does not save the configurations after executing all configurations in the template file. To save the configurations, use the **`save`** command.

Two devices with the same role can automatically set up an IRF fabric only when the IRF physical interfaces on the devices are connected.

Two IRF member devices in an IRF fabric use the following rules to elect the IRF master during automated VCF fabric deployment:

- If the uptime of both devices is shorter than two hours, the device with the higher bridge MAC address becomes the IRF master.
- If the uptime of one device is equal to or longer than two hours, that device becomes the IRF master.
- If the uptime of both devices are equal to or longer than two hours, the IRF fabric cannot be set up. You must manually reboot one of the member devices. The rebooted device will become the IRF subordinate.

If the IRF member ID of a device is not 1, the IRF master might reboot during automatic IRF fabric setup.

Procedure

1. Finish the underlay network planning (such as IP address assignment, reliability design, and routing deployment) based on user requirements.
2. Configure the DHCP server.

Configure the IP address of the device, the IP address of the TFTP server, and names of template files saved on the TFTP server. For more information, see the user manual of the DHCP server.

3. Configure the TFTP server.

   Create template files and save the template files to the TFTP server.

   The H3C DR1000 ADDC or ADCAM network management software can automatically create template files and save the files to the TFTP server. If no H3C DR1000 ADDC or ADCAM is available on the network, you must manually create template files and save the files to the TFTP server. For more information about template files, see "Template file."

4. (Optional.) Configure the NTP server.
5. Connect the device to the VCF fabric and start the device.

   After startup, the device uses a management Ethernet interface or VLAN-interface 1 to connect to the fabric management network. Then, it downloads the template file corresponding to its device role and parses the template file to complete automated VCF fabric deployment.

6. (Optional.) Save the deployed configuration.

   If the template file does not include IRF configurations, the device will not save the configurations after executing all configurations in the template file. To save the configurations, use the **save** command. For more information about this command, see configuration file management commands in *Fundamentals Command Reference*.

Enabling VCF fabric topology discovery

1. Enter system view.

   system-view

2. Enable LLDP globally.

   lldp global enable

   By default, LLDP is disabled globally.

   You must enable LLDP globally before you enable VCF fabric topology discovery, because the device needs LLDP to collect topology data of directly-connected devices.

3. Enable VCF fabric topology discovery.

   vcf-fabric topology enable

   By default, VCF fabric topology discovery is disabled.

Configuring automated underlay network deployment

Restrictions and guidelines

After automated underlay network deployment starts, you cannot use the CLI commands to modify the configuration. A violation might cause automated deployment failure. If you want to modify the configuration, first cancel or pause automated deployment. Additionally, do not start automated deployment after the modification. To cancel automated deployment, use the **undo vcf-fabric underlay autoconfigure** command. To pause automated deployment, use the **vcf-fabric underlay pause** command.

Specify the template file for automated underlay network deployment

1. Enter system view.
   system-view
2. Specify the template file for automated underlay network deployment.
   vcf-fabric underlay autoconfigure *template*
   By default, no template file is specified for automated underlay network deployment.

Pausing automated underlay network deployment

About this task

If you pause automated underlay network deployment, the VCF fabric will save the current status of the device. It will not respond to new LLDP events, set up the IRF fabric, aggregate links, or discover uplink or downlink interfaces.

Perform this task if all devices in the VCF fabric complete automated deployment and new devices are to be added to the VCF fabric.

Procedure

1. Enter system view.
   system-view
2. Pause automated underlay network deployment.
   vcf-fabric underlay pause
   By default, automated underlay network deployment is not paused.

Display and maintenance commands for VCF fabric

Execute **display** commands in any view.

Task	Command
Display the role of the device in the VCF fabric.	**display vcf-fabric role**
Display information about automated underlay network deployment.	**display vcf-fabric underlay autoconfigure**
Display the supported version and the current version of the template file for automated VCF fabric provisioning.	**display vcf-fabric underlay template-version**

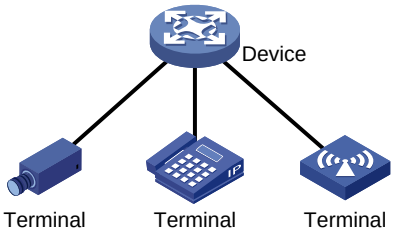
Configuring EPA

About EPA



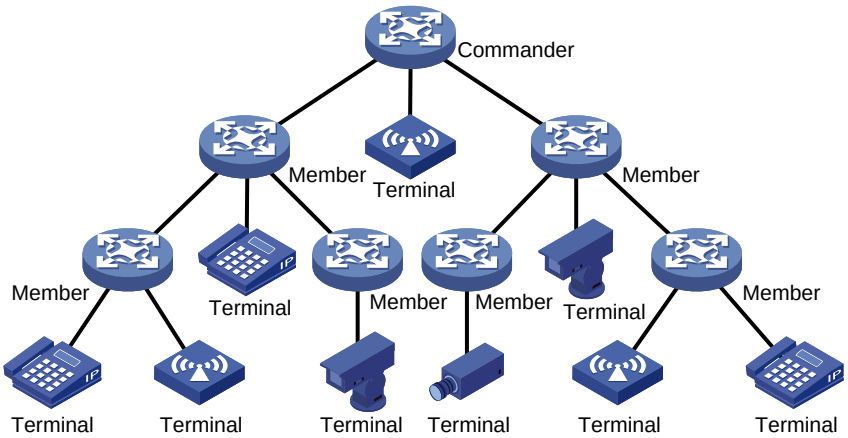
Endpoint Analysis (EPA) allows you to monitor associations and disassociations of endpoints (for example, cameras and IP phones) connecting to an H3C device.

Application scenarios

Non-SmartMC networking

As shown in Figure 1, the device configured with EPA monitors associations and disassociations of endpoints connecting to it. The device can be a standalone device or an IRF fabric. For an IRF fabric, EPA monitors endpoints connecting to all members. The collected association and disassociation information will be reported to the master device for processing.

Figure 1 Non-SmartMC networking



SmartMC networking

In a SmartMC network as shown in Figure 2, EPA settings are configured only on the commander. The members report association and disassociation information about their associated endpoints to the commander. The commander records such information about all associated endpoints in the network, and deploys EPA settings to the members.

You can view EPA information in the entire network on the commander.

Figure 2 SmartMC networking

Endpoint identification methods

EPA supports the following endpoint identification methods:

- **Static identification**—Identifies associations and disassociations of endpoints by matching MAC addresses of the endpoints. This method requires manual configuration of endpoint MAC addresses on the device and is applicable to networks with a small number of endpoints. This method can only identify cameras and cannot identify the vendor and operating system of cameras.
- **Automatic identification**—Identifies associations and disassociations of endpoints through the fields in packets. This method is applicable to networks with a large number of endpoints. This method can identify the endpoint category, vendor and operating system of endpoints. This method needs to work with BYOD.

Static endpoint identification

EPA monitors endpoint associations and disassociations by monitoring the generation and aging of MAC address entries learned by devices. A device configured with EPA can monitor only endpoints in the same subnet as the endpoint access port on the device.

For more information about MAC address entries, see *Layer 2—LAN Switching Configuration Guide*.

Collecting endpoint association information

If a device configured with EPA learns a new MAC address entry, it compares the MAC address and VLAN ID with the configured EPA monitor rules.

- If a match is found, the device determines that a monitored endpoint came online.
  - In a non-SmartMC network, the device records the endpoint association event locally.
  - In a SmartMC network, if the device is the commander, it records the endpoint association event locally. If the device is a member, it reports the event to the commander.
- If no match is found, the device determines that the endpoint is not a monitored endpoint and does not record the endpoint association event.

Collecting endpoint disassociation information

When the MAC address entry of an endpoint ages out, the device determines that the endpoint went offline.

- In a non-SmartMC network, the device records the endpoint disassociation event locally for 7 days.
- In a SmartMC network, the commander records the endpoint disassociation event for 7 days.

Synchronizing information in a SmartMC network

In a SmartMC network, endpoint monitor rules are configured on the commander and deployed to all members by the commander. The rules take effect on both the commander and members. If a member detects an association or disassociation event of a monitored endpoint, it reports the event to the commander for statistics collection and analysis.

You can view endpoint associations and disassociations that occurred in the entire network from the commander. For more information about SmartMC, see "Configuring SmartMC."

Automatic endpoint identification

As Internet technologies develop, many enterprises allow employees to use their own mobile devices (for example, mobile phones, tablets, and laptops) to access internal networks. This might create security risks. To ensure security by managing endpoints, administrators must know what endpoints are in the network, including endpoint category and endpoint operating system.

EPA can automatically identify endpoints by working with BYOD. When an endpoint accesses the network, EPA obtains fingerprint information from the authentication request of an endpoint and matches the fingerprint with the BYOD endpoint identification rules. If a match is found, EPA considers that the endpoint is online and records the MAC address, endpoint category, and vendor of the endpoint.

A BYOD endpoint identification rule is a fingerprint entry, which includes the fingerprint type, fingerprint value, endpoint category, and endpoint vendor, and endpoint OS.

BYOD supports the following endpoint fingerprints:

- **DHCP Option 55 fingerprint**—Parameter request list option. The option is used by an endpoint to request specified configuration parameters. To use this fingerprint, enable recording of client information in DHCP snooping entries on the access interface of endpoints. For more information about DHCP Option55 and DHCP snooping, see DHCP in *Layer 3—IP Services Configuration Guide*.
- **HTTP user agent fingerprint**—Located in the header of HTTP requests to carry information about the endpoint operating system, Web browser, and versions. To use this fingerprint, enable portal authentication on the access interface of endpoints. For more information about portal authentication, see DHCP in *Security Configuration Guide*.
- **MAC address fingerprint**—MAC address of the endpoint or MAC address range to which the endpoint belongs.

Static endpoint identification has higher priority than dynamic endpoint identification. The device matches fingerprint information for an endpoint in the following order:

1. DHCP Option 55 fingerprint.
2. HTTP user agent fingerprint.
3. MAC address fingerprint.

The system has predefined BYOD endpoint identification rules. You can also configure BYOD endpoint identification rules depending on the network requirements.

For more information about BYOD, see AAA in Security Configuration Guide.

Restrictions: Software version compatibility with EPA

EPA is supported only in Release 1112 and later.

Restrictions and guidelines: EPA configuration

Do not use the **mac-address dynamic** command to configure dynamic MAC address entries for monitored endpoints. If you do so, the system might fail to identify endpoint association events.

When you configure EPA in a SmartMC network, follow these restrictions and guidelines:

- Make sure all devices in the network support EPA.
- You can configure endpoint monitor rules only on the commander.
- Configure the same aging time for MAC address entries on all devices in the SmartMC network. Otherwise, endpoint association and disassociation analysis on the commander might be inaccurate. For more information about MAC address entries, see *Layer 2—LAN Switching Configuration Guide*.
- To view endpoint association and disassociation events in a SmartMC network, execute the **display epa monitor-information** command on the commander instead of a member. If you execute the command on a member, the command displays only association events of endpoints connecting to the member.

Configuring static endpoint identification

Restrictions and guidelines

When you configure static endpoint identification rules, follow these restrictions and guidelines:

- To configure multiple rules to monitor an endpoint in different VLANs, make sure the specified VLAN ranges in these rules do not overlap with each other.
- As a best practice to ensure the optimal EPA performance, specify the VLANs in which an endpoint will be monitored.
- If you configure a rule to monitor an endpoint in all VLANs, make sure the endpoint will not come online from over 10 VLANs.
- You can configure a maximum of 1024 monitor rules. As a best practice to ensure the optimal EPA performance, do not configure over 512 monitor rules.
- You can specify a rule ID when creating a monitor rule. If you do not specify the ID, the system assigns the smallest available ID to the rule.
- You cannot execute the **epa monitor-rule** command multiple times to edit an existing rule. To edit an existing rule, use the **undo epa monitor-rule** command to delete the rule and then create the rule again.

Procedure

1. Enter system view.

   system-view

2. Create a static endpoint identification rule.

   epa monitor-rule [*monitor-rule-id*] **mac** *mac-address* [**mask** *mac-mask*] [**vlan** *vlan-id*]

   By default, no static endpoint identification rules exist.

Configuring dynamic endpoint identification

Prerequisites

The system has predefined BYOD endpoint identification rules. You can also configure BYOD endpoint identification rules depending on the network requirements (see AAA in *Security Configuration Guide*).

Restrictions and guidelines

After you modify a fingerprint entry, the modified parameters are reflected for matching online endpoints only if they log out and log in again.

Procedure

1. Enter system view.

   system-view

2. Enable automatic endpoint identification.

   epa auto-identify enable

   By default, automatic endpoint identification is disabled.

Disabling EPA logging

About this task

By default, the EPA module logs endpoint associations and disassociations. If a monitored endpoint comes online or goes offline frequently, the device will generate a large number of log entries. In this case, to avoid affecting device performance, disable EPA logging as a best practice.

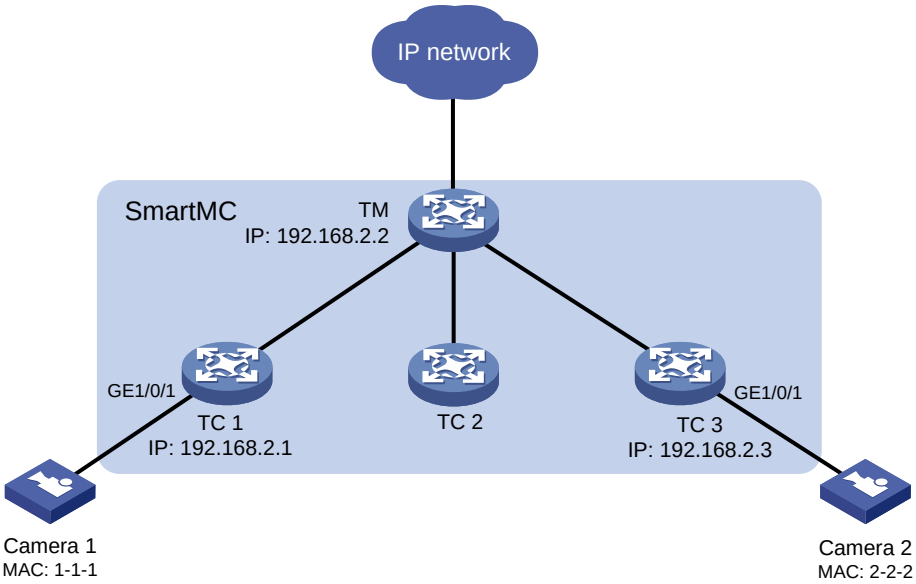
Procedure

1. Enter system view.
   `system-view`
2. Disable EPA logging.
   `epa online-offline-log disable`
   By default, EPA logging is enabled.

Display and maintenance commands for EPA

Execute **`display`** commands in any view.

Task	Command
Display endpoint association and disassociation information detected by EPA.	**`display epa monitor-information`** [**`online`** | **`offline`**] [**`device`** *`device-id`* | **`mac`** *`mac-address`* [**`vlan`** *`vlan-id`*]] [**`verbose`**]



EPA configuration examples

Example: Configuring EPA

Network configuration

As shown in Figure 3, the SmartMC network is established manually. Configure the devices in SmartMC network so EPA can automatically identify camera 1 and camera 2 when they access the SmartMC network.

Figure 3 Network diagram

Configuring the TM

1. Configure SmartMC:

   # Configure VLAN-interface 1.

   ```
   [TM] interface vlan-interface 1
   [TM-Vlan-interface1] ip address 192.168.2.2 24
   [TM-Vlan-interface1] quit
   ```

   # Enable HTTP and HTTPS.

   ```
   [TM] ip http enable
   [TM] ip https enable
   ```

   # Enable the Telnet service.

   ```
   [TM] telnet server enable
   ```

   # Enable NETCONF over SOAP over HTTP.

   ```
   [TM] netconf soap http enable
   ```

   # Enable LLDP globally.

   ```
   [TM] lldp global enable
   ```

   # Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

   ```
   [TM] local-user admin
   [TM-luser-manage-admin] password simple hello12345
   [TM-luser-manage-admin] service-type telnet http https
   [TM-luser-manage-admin] authorization-attribute user-role network-admin
   [TM-luser-manage-admin] quit
   ```

   # Set scheme authentication for VTY user lines 0 to 63.

   ```
   [TM] line vty 0 63
   [TM-line-vty0-63] authentication-mode scheme
   [TM-line-vty0-63] quit
   ```

   # Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

   ```
   [TM] smartmc tm username admin password simple hello12345 enable
   ```

2. Configure static endpoint identification rules on the commander.

```
[TM] epa monitor-rule mac 1-1-1
[TM] epa monitor-rule mac 2-2-2
```

Configuring TC 1

1. Configure SmartMC:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.1 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user named **admin**.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

Configuring TC 3

Configure TC 3 in the same way TC 1 is configured. (Details not shown.)

Verifying the configuration

On TC 1, display the online and offline information of endpoints.

```
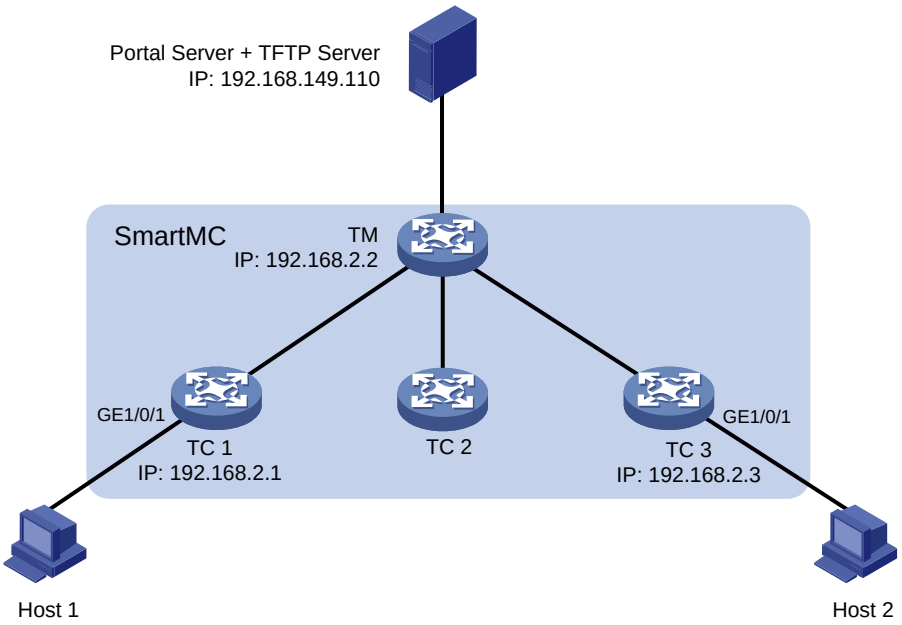
[TC1] display epa monitor-information
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Endpoint information:
  Access device ID   MAC address    VLAN   Interface              Status
```

```
  3acc-58e2-0100     0001-0001-0001  1       GE1/0/1                 Online
```

On the TM, display the online and offline information of endpoints.



```
[TM] display epa monitor-information
Local device type    : SmartMC TM
Local device ID     : 3acc-58e2-0100
Endpoint information:
  Access device ID    MAC address     VLAN    Interface               Status
  3acc-58e2-0100     0001-0001-0001  1       GE1/0/1                  Online
  3acc-58e2-0300     0002-0002-0002  1       GE1/0/1                  Online
```

Example: Configuring automatic endpoint identification (portal authentication)

Network configuration

As shown in Figure 4, the SmartMC network is established automatically. Configure the devices in SmartMC network so EPA can automatically identify host 1 and host 2 when they access the SmartMC network through portal authentication.

Figure 4 Network diagram

Configuring the TM

1. Configure SmartMC:

   # Configure VLAN-interface 1.

   ```
   [TM] interface vlan-interface 1
   [TM-Vlan-interface1] ip address 192.168.2.1 24
   [TM-Vlan-interface1] quit
   ```

   # Enable HTTP and HTTPS.

   ```
   [TM] ip http enable
   [TM] ip https enable
   ```

   # Enable the Telnet service.

   ```
   [TM] telnet server enable
   ```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

2. Enable EPA automatic endpoint identification on the commander.

```
[TM] epa auto-identify enable
```

Configuring TC 1

1. Configure SmartMC:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.2 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user named **admin**.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
```

```
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

2. Configure portal authentication:

Create an ISP domain named **dm1** and enter its view.

```
[TC1] domain dm1
```

Configure AAA methods for the ISP domain.

```
[TC1-isp-dm1] authentication portal local
[TC1-isp-dm1] authorization portal local
[TC1-isp-dm1] accounting portal local
[TC1-isp-dm1] quit
```

Configure a portal Web server.

```
[TC1] portal web-server newpt
[TC1-portal-websvr-newpt] url http://192.168.149.110:2331/portal
[TC1-portal-websvr-newpt] quit
```

Enable direct portal authentication on GigabitEthernet 1/0/1.

```
[TC1] interface gigabitethernet 1/0/1
[TC1-GigabitEthernet1/0/1] port link-mode route
[TC1-GigabitEthernet1/0/1] ip address 192.168.149.110 16
[TC1-GigabitEthernet1/0/1] portal enable method direct
```

Specify portal Web server **newpt** on GigabitEthernet 1/0/1.

```
[TC1-GigabitEthernet1/0/1] portal apply web-server newpt
[TC1-GigabitEthernet1/0/1] quit
[TC1] quit
```

Download an authentication page file from a TFTP server.

```
<TC1> tftp 192.168.149.110 get defaultfile.zip
```

Create an HTTP-based local portal Web service and enter its view.

```
<TC1> system-view
[TC1] portal local-web-server http
```

Specify file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the file exist under the root directory of the router.)

```
[TC1-portal-local-websvr-http] default-logon-page defaultfile.zip
```

Set the HTTP listening port number to 2331 for the local portal Web service.

```
[TC1-portal-local-websvr-http] tcp-port 2331
[TC1-portal-local-websvr-http] quit
```

3. Configure a BYOD endpoint identification rule:

Configure a rule to identify BYOD endpoints containing HTTP UserAgent fingerprint **Mozilla/5.0**.

```
[TC1] byod rule http-user-agent Mozilla/5.0 device-attributes
```

Configure at least one piece of the following fingerprint information.

```
[TC1-byod-ua-Mozilla/5.0] device-category PC
[TC1-byod-ua-Mozilla/5.0] device-vendor Xerox
```

```
[TC1-byod-ua-Mozilla/5.0] device-os "Window Vista/7 or Server 2008 (Version 6.0)"
[TC1-byod-ua-Mozilla/5.0] quit
```

Configuring TC 3

Configure TC 3 in the same way TC 1 is configured. (Details not shown.)

Verifying the configuration

On TC 1, verify that EPA can successfully identify the hosts when they come online.

```
[TC1] display epa monitor-information verbose
Auto identification : Enabled
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Total endpoints identified by EPA: 1
Access device ID: 3acc-58e2-0100
  MAC address   : 0a00-2700-0010           VLAN  : -
  IP address    : 192.168.226.1
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Windows Vista/7 or Server 2008 (Version 6.0)
```

On the TM, verify that EPA can successfully identify the hosts when they come online.

```
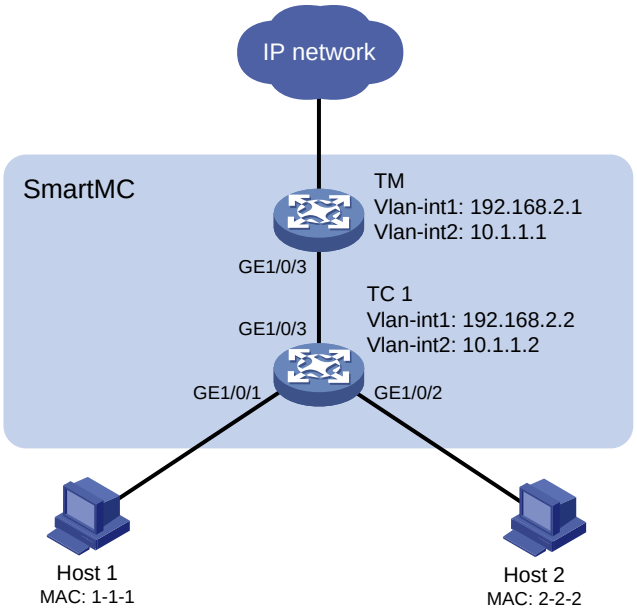
[TM] display epa monitor-information verbose
Auto identification : Enabled
Local device type    : SmartMC TM
Local device ID     : 90bc-1b85-0300
Total endpoints identified by EPA: 2

Access device ID: 3acc-58e2-0100
  MAC address    : 0001-0001-0001           VLAN  : -
  IP address     : 192.168.226.1
  Interface      : GigabitEthernet1/0/1     Status: Online
  Category       : PC                       Vendor: Xerox
  OS            : Windows Vista/7 or Server 2008 (Version 6.0)



Access device ID: 3acc-58e2-0300
  MAC address    : 0002-0002-0002           VLAN  : -
  IP address     : 192.168.226.2
  Interface      : GigabitEthernet1/0/1     Status: Online
  Category       : PC                       Vendor: Xerox
  OS            : Windows Vista/7 or Server 2008 (Version 6.0)
```

Example: Configuring automatic endpoint identification (DHCP)

Network configuration

As shown in Figure 5, the SmartMC network is established automatically. Configure the devices in SmartMC network so EPA can automatically identify host 1 and host 2 when they access the SmartMC network through DHCP.

Figure 5 Network diagram

Configuring the TM

1. Configure SmartMC:

Configure VLAN-interface 1.

```
[TM] interface vlan-interface 1
[TM-Vlan-interface1] ip address 192.168.2.1 24
[TM-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TM] ip http enable
[TM] ip https enable
```

Enable the Telnet service.

```
[TM] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

2. Configure the DHCP server:

   # Configure VLAN-interface 2.

```
<TM> system-view
[TM] vlan 2
[TM-vlan2] quit
[TM] interface vlan-interface 2
[TM-Vlan-interface2] ip address 10.1.1.1 24
[TM-Vlan-interface2] quit
```

   # Exclude the IP address of the DNS server from dynamic allocation.

```
[TM] dhcp server forbidden-ip 10.1.1.2
```

   # Configure DHCP address pool 0 to assign IP addresses and other configuration parameters to clients on subnet 10.1.1.0/24.

```
[TM] dhcp server ip-pool 0
[TM-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
[TM-dhcp-pool-0] expired day 10
[TM-dhcp-pool-0] quit
```

   # Enable DHCP.

```
[RouterA] dhcp enable
```

3. Enable EPA automatic endpoint identification on the commander.

```
[TM] epa auto-identify enable
```

4. Configure GigabitEthernet 1/0/3.

```
[TM] interface gigabitethernet 1/0/3
[TM-GigabitEthernet1/0/3] port link-type trunk
[TM-GigabitEthernet1/0/3] port trunk permit vlan all
```

Configuring TC 1

1. Configure SmartMC:

   # Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.2 24
[TC1-Vlan-interface1] quit
```

   # Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

   # Enable the Telnet service.

```
[TC1] telnet server enable
```

   # Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

   # Enable LLDP globally.

```
[TC1] lldp global enable
```

   # Create a user named **admin**.

```
[TC1] local-user admin
```

   # Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

2. Configure DHCP snooping:

Enable DHCP snooping globally.

```
<TC1> system-view
[TC1] dhcp snooping enable
```

Assign an IP address to VLAN-interface 2.

```
[TC1] vlan 2
[TC1-vlan2] quit
[TC1] interface vlan-interface 2
[TC1-Vlan-interface2] ip address 10.1.1.2 24
[TC1-Vlan-interface2] quit
```

Assign GigabitEthernet 1/0/1 to VLAN 2, and configure it as a trusted port.

```
[TC1] interface gigabitethernet 1/0/1
[TC1-GigabitEthernet1/0/1] port access vlan 2
[TC1-GigabitEthernet1/0/1] dhcp snooping trust
[TC1-GigabitEthernet1/0/1] quit
```

Assign GigabitEthernet 1/0/2 to VLAN 2, and configure it as a trusted port.

```
[TC1] interface gigabitethernet 1/0/2
[TC1-GigabitEthernet1/0/2] port access vlan 2
[TC1-GigabitEthernet1/0/2] dhcp snooping trust
[TC1-GigabitEthernet1/0/2] quit
```

3. Configure GigabitEthernet 1/0/3.

```
[TC1] interface gigabitethernet 1/0/3
[TC1-GigabitEthernet1/0/3] port link-type trunk
[TC1-GigabitEthernet1/0/3] port trunk permit vlan all
```

4. Configure a BYOD endpoint identification rule:

If you use the default fingerprint information, skip this step.

Configure a rule to identify BYOD endpoints containing DHCP Option55 fingerprint **1,121,3,6,12,15,33,43,66,67,138,150**.

```
[TC1] byod rule dhcp-option 1,121,3,6,12,15,33,43,66,67,138,150 device-attribute
```

Configure at least one piece of the following fingerprint information.

```
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-category PC
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-vendor Xerox
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-os "Window Vista/7 or
Server 2008 (Version 6.0)"
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] quit
```

5. Configure host 1 and host 2 to obtain IP addresses through DHCP.

Verifying the configuration

On TC 1, verify that EPA can successfully identify the hosts when they come online.

```
[TC1] display epa monitor-information verbose
Auto identification : Enabled
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Total endpoints identified by EPA: 2
Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : 2
  IP address    : 10.1.1.3
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)
Access device ID: 3acc-58e2-0100
  MAC address   : 0002-0002-0002           VLAN  : 2
  IP address    : 10.1.1.4
  Interface     : GigabitEthernet1/0/2     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)
```

On the TM, verify that EPA can successfully identify the hosts when they come online.

```
[TM] display epa monitor-information verbose
Auto identification : Enabled
Local device type    : SmartMC TM
Local device ID     : 90bc-1b85-0300
Total endpoints identified by EPA: 2
Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : 2
  IP address    : 10.1.1.3
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)
Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : 2
  IP address    : 10.1.1.4
  Interface     : GigabitEthernet1/0/2     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)
```

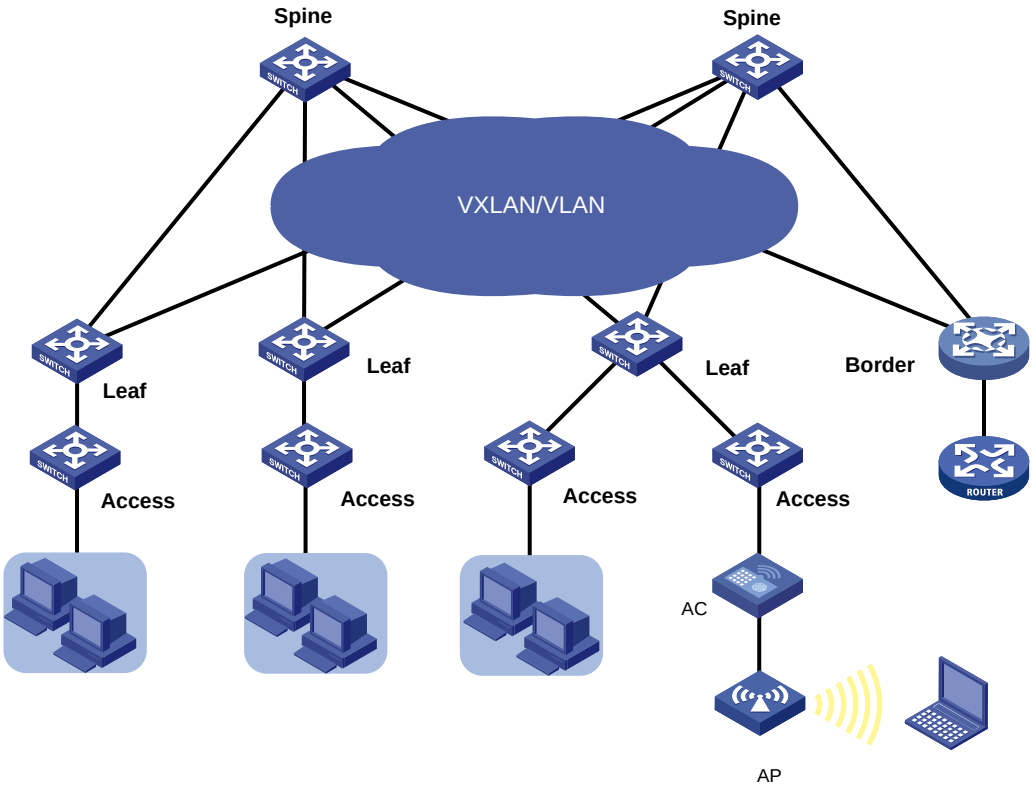
Configuring VCF fabric

About VCF fabric

Based on OpenStack Networking (Neutron), the Virtual Converged Framework (VCF) solution provides virtual network services from Layer 2 to Layer 7 for cloud tenants. This solution breaks the boundaries between the network, cloud management, and terminal platforms and transforms the IT infrastructure to a converged framework to accommodate all applications. It also implements automated topology discovery and automated deployment of underlay networks and overlay networks to reduce the administrators' workload and speed up network deployment and upgrade.

VCF fabric topology

VCF fabric topology for a campus network



In a campus VCF fabric, a device has one of the following roles:

- **Spine node**—Connects to leaf nodes.
- **Leaf node**—Connects to access nodes.
- **Access node**—Connects to an upstream leaf node and downstream terminal devices. Cascading of access nodes is supported.
- **Border node**—Located at the border of a VCF fabric to provide access to the external network.

Spine nodes and leaf nodes form a large Layer 2 network.

The switch series can be used only as access nodes.

Figure 1 VCF fabric topology for a campus network

Automated VCF fabric deployment

VCF provides the following features to ease deployment:

- Automated topology discovery.

  In a VCF fabric, each device uses LLDP to collect local topology information from directly-connected peer devices. The local topology information includes connection interfaces, roles, MAC addresses, and management interface addresses of the peer devices. If multiple spine nodes exist in a VCF fabric, the master spine node collects the topology for the entire network.

- Automated underlay network deployment.

  Automated underlay network deployment sets up a Layer 3 underlay network (a physical Layer 3 network) for users. It is implemented by automatically executing configurations (such as IRF configuration and Layer 3 reachability configurations) in user-defined template files.

Process of automated VCF fabric deployment

The device finishes automated VCF fabric deployment as follows:

1. Starts up without loading configuration and then obtains an IP address, the IP address of the TFTP server, and a template file name from the DHCP server.
2. Determines the name of the template file to be downloaded based on the device role and the template file name obtained from the DHCP server. For example, 1_leaf**.template** represents a template file for leaf nodes.
3. Downloads the template file from the TFTP server.
4. Parses the template file and performs the following operations:

- Deploys static configurations that are independent from the VCF fabric topology.
- Deploys dynamic configurations according to the VCF fabric topology.

  The topology process notifies the automation process of creation, deletion, and status change of neighbors. Based on the topology information, the automation process completes role discovery, automatic aggregation, and IRF fabric setup.

Template file

A template file contains the following contents:

- **System-predefined variables**—The variable names cannot be edited, and the variable values are set by the VCF topology discovery feature.
- **User-defined variables**—The variable names and values are defined by the user. These variables include the username and password used to establish a connection with the RabbitMQ server, network type, and so on. The following are examples of user-defined variables:

  ```
  #USERDEF
  _username = aaa
  _password = hello12345
  _rbacUserRole = network-admin
  _loghost_ip = 172.16.1.136
  ……
  ```

- **Static configurations**—Static configurations are independent from the VCF fabric topology and can be directly executed. The following are examples of static configurations:

  ```
  #STATICCFG
  #
   clock timezone beijing add 08:00:00
  #
   lldp global enable
  #
   stp global enable
  #
  ```

- **Dynamic configurations**—Dynamic configurations are dependent on the VCF fabric topology. The device first obtains the topology information through LLDP and then executes dynamic configurations. The following are examples of dynamic configurations:

  ```
  #
  interface $$_underlayIntfDown
   port link-mode route
   ip address unnumbered interface LoopBack0
   ospf 1 area 0.0.0.0
   ospf network-type p2p
   lldp management-address arp-learning
   lldp tlv-enable basic-tlv management-address-tlv interface LoopBack0
  #
  ```

VCF fabric task at a glance

To configure a VCF fabric, perform the following tasks:

- Configuring automated VCF fabric deployment

No tasks are required to be made on the device for automated VCF fabric deployment. However, you must make related configuration on the DHCP server and the TFTP server so the device can download and parse a template file to complete automated VCF fabric deployment.

- (Optional.) Adjust VCF fabric deployment

  If the device cannot obtain or parse the template file to complete automated VCF fabric deployment, choose the following tasks as needed:

  - Enabling VCF fabric topology discovery
  - Configuring automated underlay network deployment

Configuring automated VCF fabric deployment

Restrictions and guidelines

The default role of the switch in the VCF fabric of a campus network is an access node. You cannot change its role.

On a campus network, links between two access nodes cascaded through GigabitEthernet interfaces and links between leaf nodes and access nodes are automatically aggregated. For links between spine nodes and leaf nodes, the **`trunk permit vlan`** command is automatically executed.

On a campus network where multiple leaf nodes that have an access node attached form an IRF fabric, make sure only one link exists between each leaf node and its connected access node.

Do not perform link migration when devices in the VCF fabric are in the process of coming online or powering down after the automated VCF fabric deployment finishes. A violation might cause link-related configuration fails to update.

The version format of a template file for automated VCF fabric deployment is *x*.*y*. Only the *x* part is examined during a version compatibility check. For successful automated deployment, make sure *x* in the version of the template file to be used is not greater than *x* in the supported version. To display the supported version of the template file for automated VCF fabric deployment, use the **`display vcf-fabric underlay template-version`** command.

If the template file does not include IRF configurations, the device does not save the configurations after executing all configurations in the template file. To save the configurations, use the **`save`** command.

Two devices with the same role can automatically set up an IRF fabric only when the IRF physical interfaces on the devices are connected.

Two IRF member devices in an IRF fabric use the following rules to elect the IRF master during automated VCF fabric deployment:

- If the uptime of both devices is shorter than two hours, the device with the higher bridge MAC address becomes the IRF master.
- If the uptime of one device is equal to or longer than two hours, that device becomes the IRF master.
- If the uptime of both devices are equal to or longer than two hours, the IRF fabric cannot be set up. You must manually reboot one of the member devices. The rebooted device will become the IRF subordinate.

If the IRF member ID of a device is not 1, the IRF master might reboot during automatic IRF fabric setup.

Procedure

1. Finish the underlay network planning (such as IP address assignment, reliability design, and routing deployment) based on user requirements.

2. Configure the DHCP server.

   Configure the IP address of the device, the IP address of the TFTP server, and names of template files saved on the TFTP server. For more information, see the user manual of the DHCP server.

3. Configure the TFTP server.

   Create template files and save the template files to the TFTP server.

   The H3C DR1000 ADDC or ADCAM network management software can automatically create template files and save the files to the TFTP server. If no H3C DR1000 ADDC or ADCAM is available on the network, you must manually create template files and save the files to the TFTP server. For more information about template files, see "Template file."

4. (Optional.) Configure the NTP server.

5. Connect the device to the VCF fabric and start the device.

   After startup, the device uses a management Ethernet interface or VLAN-interface 1 to connect to the fabric management network. Then, it downloads the template file corresponding to its device role and parses the template file to complete automated VCF fabric deployment.

6. (Optional.) Save the deployed configuration.

   If the template file does not include IRF configurations, the device will not save the configurations after executing all configurations in the template file. To save the configurations, use the **`save`** command. For more information about this command, see configuration file management commands in *Fundamentals Command Reference*.

Enabling VCF fabric topology discovery

1. Enter system view.

   `system-view`

2. Enable LLDP globally.

   `lldp global enable`

   By default, LLDP is disabled globally.

   You must enable LLDP globally before you enable VCF fabric topology discovery, because the device needs LLDP to collect topology data of directly-connected devices.

3. Enable VCF fabric topology discovery.

   `vcf-fabric topology enable`

   By default, VCF fabric topology discovery is disabled.

Configuring automated underlay network deployment

Restrictions and guidelines

After automated underlay network deployment starts, you cannot use the CLI commands to modify the configuration. A violation might cause automated deployment failure. If you want to modify the configuration, first cancel or pause automated deployment. Additionally, do not start automated deployment after the modification. To cancel automated deployment, use the **`undo vcf-fabric underlay autoconfigure`** command. To pause automated deployment, use the **`vcf-fabric underlay pause`** command.

Specify the template file for automated underlay network deployment

1. Enter system view.
   system-view
2. Specify the template file for automated underlay network deployment.
   vcf-fabric underlay autoconfigure *template*
   By default, no template file is specified for automated underlay network deployment.

Pausing automated underlay network deployment

About this task

If you pause automated underlay network deployment, the VCF fabric will save the current status of the device. It will not respond to new LLDP events, set up the IRF fabric, aggregate links, or discover uplink or downlink interfaces.

Perform this task if all devices in the VCF fabric complete automated deployment and new devices are to be added to the VCF fabric.

Procedure

1. Enter system view.
   system-view
2. Pause automated underlay network deployment.
   vcf-fabric underlay pause
   By default, automated underlay network deployment is not paused.

Display and maintenance commands for VCF fabric

Execute **display** commands in any view.

Task	Command
Display the role of the device in the VCF fabric.	**display vcf-fabric role**
Display information about automated underlay network deployment.	**display vcf-fabric underlay autoconfigure**
Display the supported version and the current version of the template file for automated VCF fabric provisioning.	**display vcf-fabric underlay template-version**

H3C S5170-EI Switch Series

Telemetry Configuration Guide

Notice

The information in this document is subject to change without notice. All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes gRPC features and configuration tasks.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators working with the S5170-EI switch series.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring gRPC

About gRPC

gRPC is an open source remote procedure call (RPC) system initially developed at Google. It uses HTTP 2.0 and provides network device configuration and management methods that support multiple programming languages.

gRPC protocol stack layers

Table 1 describes the gRPC protocol stack layers.

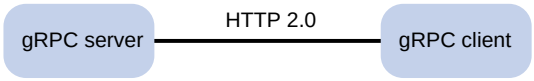

Table 1 gRPC protocol stack layers

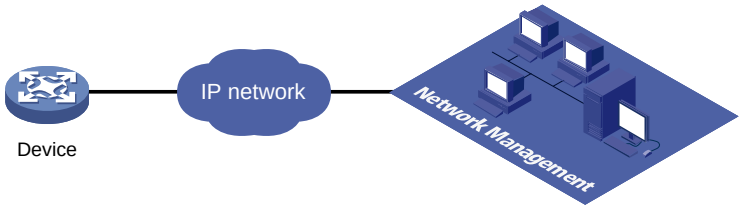
Layer	Description
Content layer	Defines the data of the service module. Two peers must notify each other of the data models that they are using.
Protocol buffer encoding layer	Encodes data by using the protocol buffer code format.
gRPC layer	Defines the protocol interaction format for remote procedure calls.
HTTP 2.0 layer	Carries gRPC.
TCP layer	Provides connection-oriented reliable data links.

Network architecture

As shown in Figure 1, the gRPC network uses the client/server model. It uses HTTP 2.0 for packet transport.

Figure 1 gRPC network architecture

The gRPC network uses the following mechanism:



1. The gRPC server listens to connection requests from clients at the gRPC service port.
2. A user runs the gRPC client application to log in to the gRPC server, and uses methods provided in the .proto file to send requests.
3. The gRPC server responds to requests from the gRPC client.

The device can act as the gRPC server or client.

Telemetry technology based on gRPC

Telemetry is a remote data collection technology for monitoring device performance and operating status. H3C telemetry technology uses gRPC to push data from the device to the collectors on the NMSs. As shown in Figure 2, after a gRPC connection is established between the device and NMSs, the NMSs can subscribe to data of modules on the device.

Figure 2 Telemetry technology based on gRPC

Telemetry modes

The device supports the following telemetry modes:

- **Dial-in mode**—The device acts as a gRPC server and the collectors act as gRPC clients. A collector initiates a gRPC connection to the device to subscribe to device data.

  Dial-in mode supports the following operations:

  - **Get**—Obtains device status and settings.
  - **CLI**—Executes commands on the device.
  - **gNMI**—gRPC Network Management Interface operations, which include the following subtypes of operations:
    - **gNMI Capabilities**—Obtains the capacities of the device.
    - **gNMI Get**—Obtains the status and settings of the device.
    - **gNMI Set**—Deploys settings to the device.
    - **gNMI Subscribe**—Subscribes to data push services provided by the device. The data might be generated by periodical data collection or event-triggered data collection.
- **Dial-out mode**—The device acts as a gRPC client and the collectors act as gRPC servers. The device initiates gRPC connections to the collectors and pushes device data to the collectors as configured.

gNMI

gRPC Network Management Interface (gNMI) is a gRPC-based protocol for network device management. It defines a series of RPC methods to obtain or configure the states of devices.

The device supports gNMI and non-gNMI subscriptions for pushing data to a collector.

Protocols

RFC 7540, *Hypertext Transfer Protocol version 2 (HTTP/2)*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

gRPC is not supported in FIPS mode.

Restrictions and guidelines: gRPC configuration

Disabling the gRPC service deletes all gRPC-related settings.

Configuring the gRPC dial-in mode

gRPC dial-in mode configuration tasks at a glance

To configure the gRPC dial-in mode, perform the following tasks:

1. Configuring the gRPC service
2. (Optional.) Specifying the PKI domain for secure communication with collectors
3. Configuring a gRPC user
4. (Optional.) Enabling gRPC logging in dial-in mode

Configuring the gRPC service

1. Enter system view.
   system-view
2. Enable the gRPC service.
   grpc enable
   By default, the gRPC service is disabled.
3. (Optional.) Set the gRPC service port number.
   grpc port *port-number*
   By default, the gRPC service port number is 50051.
4. (Optional.) Set the gRPC session idle timeout timer.
   grpc idle-timeout *minutes*
   By default, the gRPC session idle timeout timer is 5 minutes.

Specifying the PKI domain for secure communication with collectors

About this task

By default, the gRPC connection between the device and a collector does not provide data encryption service or require authentication. After you specify a PKI domain, the device and the collector will use TLS for data encryption and bidirectional certificate-based authentication to improve communication security.

Restrictions and guidelines

The specified PKI domain must already exist and has correct certificate and key settings. For more information about PKI domains, see PKI configuration in *Security Configuration Guide*.

After you specify the PKI domain, the gRPC service will reboot, closing the connections to collectors. The collectors must re-initiate the connections.

Procedure

1. Enter system view.
   system-view

2. Specify the PKI domain for secure communication with collectors.

   grpc pki domain *domain-name*

   By default, no PKI domain is specified for secure communication with collectors.

Configuring a gRPC user

About this task

For gRPC clients to establish gRPC sessions with the device, you must configure local users for the gRPC clients.

Procedure

1. Enter system view.

   system-view

2. Add a local user with the device management right.

   local-user *user-name* [**class manage**]

3. Configure a password for the user.

   password [{ **hash** | **simple** } *password*]

   By default, no password is configured for a local user. A non-password-protected user can pass authentication after providing the correct username and passing attribute checks.

4. Assign user role network-admin to the user.

   authorization-attribute user-role *user-role*

   By default, a local user is assigned the network-operator role.

5. Authorize the user to use the HTTPS service.

   service-type https

   By default, no service types are authorized to a local user.

For more information about the **local-user**, **password**, **authorization-attribute**, and **service-type** commands, see AAA commands in *Security Command Reference*.

Enabling gRPC logging in dial-in mode

About this task

To identify gRPC issues, enable gRPC operations logging in dial-in mode.

This feature generates gRPC operation logs in dial-in mode and sends them to the information center.

With the information center, you can configure log destinations and output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

gRPC operation logging might degrade device performance if gRPC operations are frequent. As a best practice, use gRPC operation logging only when necessary and log only gRPC operations of interest if gRPC operation logging is enabled.

Procedure

1. Enter system view.

   system-view

2. Enable gRPC logging in dial-in mode. Choose the options to configure as needed:
   - Enable gRPC logging for RPC operations in dial-in mode.

grpc log dial-in rpc { all | { cli | get }* }

By default, gRPC logging is disabled for RPC operations in dial-in mode.

- Enable gRPC logging for gNMI operations in dial-in mode.

  grpc log dial-in gnmi { all | { capabilities | get | set | subscribe }* }

  By default, gRPC logging is enabled for gNMI Set operations and disabled for other gNMI operations in dial-in mode.

Configuring the gRPC dial-out mode

gRPC dial-out mode configuration tasks at a glance

To configure the gRPC dial-out mode, perform the following tasks:

1. Enabling the gRPC service
2. (Optional.) Specifying the PKI domain for secure communication with collectors
3. Configuring sensors
4. Configuring collectors
5. Configuring a subscription
6. (Optional.) Enabling gRPC logging in dial-out mode

Enabling the gRPC service

1. Enter system view.

   system-view
2. Enable the gRPC service.

   grpc enable

   By default, the gRPC service is disabled.

Specifying the PKI domain for secure communication with collectors

About this task

By default, the gRPC connection between the device and a collector does not provide data encryption service or require authentication. After you specify a PKI domain, the device and the collector will use TLS for data encryption and bidirectional certificate-based authentication to improve communication security.

Restrictions and guidelines

The specified PKI domain must already exist and has correct certificate and key settings. For more information about PKI domains, see PKI configuration in *Security Configuration Guide*.

After you specify the PKI domain, the gRPC service will reboot, closing the connections to collectors. The device will automatically re-initiate the connections.

Procedure

1. Enter system view.

   system-view
2. Specify the PKI domain for secure communication with collectors.

grpc pki domain *domain-name*

By default, no PKI domain is specified for secure communication with collectors.

Configuring sensors

About this task

A sensor is a data path from which the device collects data and then pushes the data to a collector. You can create a sensor group and then specify sensor paths in the group. Sensor groups include non-gNMI sensor groups and gNMI sensor groups. If the collector uses gNMI, you must create gNMI sensor groups.

A sensor path supports either event-trigged or periodic data collection.

- **Event-triggered**—The device pushes data from the sensor path to the collector when certain events occur. For information about event-triggered sensor paths, see *NETCONF XML API Event Reference* for the module.
- **Periodic**—The device pushes data from the sensor path to the collector at intervals. For information about periodic sensor paths, see the NETCONF XML API references for the module except for *NETCONF XML API Configuration Reference* and *NETCONF XML API Data Reference*.
- **Condition-triggered**—The device checks the data of the sensor path periodically and pushes the data from the sensor path to the collector when certain conditions are met. For information about condition-triggered sensor paths, the sensor path check interval, and data push conditions, contact H3C Support.

  Condition-triggered sensor paths are supported only by gNMI sensor groups.

Restirctions and guidelines

As a best practice for the device to push data from sensor paths, specify sensor paths of the same type in a sensor group.

Configuring a non-gNMI sensor group

1. Enter system view.

   system-view
2. Enter telemetry view.

   telemetry
3. Create a non-gNMI sensor group and enter sensor group view.

   sensor-group *group-name*
4. Specify a sensor path.

   sensor path *path* [**selection-nodes** *node-list*]

   To specify multiple sensor paths, execute this command multiple times. If you execute this command multiple times with the same sensor path specified, the most recent configuration takes effect.

Configuring a gNMI sensor group

1. Enter system view.

   system-view
2. Enter telemetry view.

   telemetry
3. Create a gNMI sensor group and enter sensor group view.

   sensor-group *group-name* **gnmi**

To enter the view of an existing gNMI sensor group, you do not need to specify the **gnmi** keyword.

4. Specify a sensor path.

   sensor path *path* [**selection-nodes** *node-list*]

   To specify multiple sensor paths, execute this command multiple times.

Configuring collectors

About this task

Collectors are used to receive sampled data from network devices. For the device to communicate with collectors, you must create a destination group and add collectors to the destination group.

Restrictions and guidelines

As a best practice, configure a maximum of five destination groups. If you configure too many destination groups, system performance might degrade.

Prerequisites

To configure a collector that resides in a VPN instance, configure the VPN instance first.

Procedure

1. Enter system view.

   system-view

2. Enter telemetry view.

   telemetry

3. Create a destination group and enter destination group view.

   destination-group *group-name*

4. Specify a collector.

   IPv4:

   ipv4-address *ipv4-address* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

   IPv6:

   ipv6-address *ipv6-address* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

   The IPv6 address cannot be a link-local address. For more information about link-local addresses, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*.

   To specify multiple collectors, execute this command multiple times. One collector must have a different address, port, or VPN instance than the other collectors.

Configuring a subscription

About this task

A subscription binds sensor groups to destination groups. Then, the device pushes data from the specified sensors to the collectors in the destination groups.

Subscriptions include non-gNMI subscriptions and gNMI subscriptions. To push data to a collector that uses gNMI, you must configure a gNMI subscription.

Restrictions and guidelines

For a non-gNMI subscription, specify non-gNMI sensor groups.

For a gNMI subscription, specify gNMI sensor groups.

You cannot use a destination group in both a gRPC subscription and a gNMI subscription.

For the device to correctly push data from sensor paths in a sensor group, make sure the subscription settings for the sensor paths are compliant with Table 2.

Table 2 Compatibility of sensor path types and subscription settings

Sensor path type	Push mode	Data push interval	Data push suppression interval
Periodical	Default	Configured	Not configured
Event-triggered	Default	Not configured	Not configured
Condition-triggered	Condition-triggered	Not configured	Configured

Procedure

1. Enter system view.

   system-view

2. Enter telemetry view.

   telemetry

3. Create a subscription and enter subscription view.
   - Create a non-gNMI subscription and enter subscription view.

     subscription *subscription-name*
   - Create a gNMI subscription and enter subscription view.

     subscription *subscription-name* **gnmi**

     To enter the view of an existing gNMI subscription, you do not need to specify the **gnmi** keyword.

4. (Optional.) Set the data push mode.

   push-mode condition-triggered

   Perform this step only if a sensor group specified for a subscription contains condition-triggered sensor paths.

   This command is available only for gNMI subscriptions.

   By default, the data push mode for a sensor path in a subscription is periodical or event-triggered.

5. (Optional.) Set the DSCP value for packets sent to collectors.

   dscp *dscp-value*

   By default, the DSCP value for packets sent to collectors is 0.

   A greater DSCP value represents a higher priority.

6. (Optional.) Specify the source IP address for packets sent to collectors.

   source-address { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, the device uses the primary IP address of the output interface for the route to the collectors as the source address.

   Changing the source IP address for packets sent to collectors causes the device to re-establish the connection to the gRPC server.

7. Specify a sensor group.

   sensor-group *group-name* [**sample-interval** [**msec**] *interval* | **suppress-time** *suppress-time*]

   By default, no sensor groups are specified.

Parameter	Description
sample-interval	Data push interval. Specify this parameter only for periodic sensor paths.
suppress-time	Data push suppression interval. Specify this parameter only for condition-triggered sensor paths.

8. Specify a destination group.
   destination-group *group-name*
   By default, no destination groups are specified.

Enabling gRPC logging in dial-out mode

About this task

To identify gRPC issues, enable gRPC data collection logging in dial-out mode.

This feature generates gRPC data collection logs in dial-out mode and sends them to the information center.

With the information center, you can configure log destinations and output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

gRPC logging in dial-out mode is unavailable for gNMI subscriptions.

Procedure

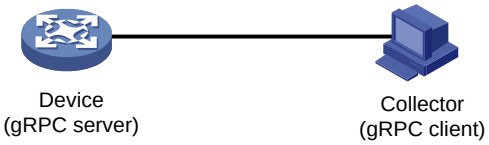
1. Enter system view.
   system-view
2. Enable gRPC logging in dial-out mode.
   grpc log dial-out { **all** | { **event** | **sample** }* }
   By default, gRPC logging is disabled in dial-out mode.

Display and maintenance commands for gRPC

Execute **display** commands in any view.

Task	Command
Display gRPC dial-in mode information.	**display grpc**

gRPC configuration examples



These configuration examples describe only CLI configuration tasks on the device. The collectors need to run an extra application. For information about collector-side application development, see "Developing the collector-side application."

Example: Configuring the gRPC dial-in mode

Network configuration

As shown in Figure 3, configure the gRPC dial-in mode on the device so the device acts as the gRPC server and the gRPC client can subscribe to LLDP events on the device.

Figure 3 Network diagram

Procedure

1. Assign IP addresses to interfaces on the gRPC server and client and configure routes. Make sure the server and client can reach each other.
2. Configure the device as the gRPC server:

   # Enable the gRPC service.

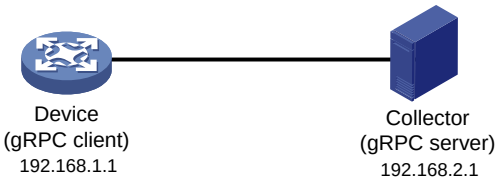
   ```
   <Device> system-view
   [Device] grpc enable
   ```

   # Create a local user named **test**. Set the password of the user, and assign user role network-admin and the HTTPS service to the user.

   ```
   [Device] local-user test
   [Device-luser-manage-test] password simple 123456TESTplat&!
   [Device-luser-manage-test] authorization-attribute user-role network-admin
   [Device-luser-manage-test] service-type https
   [Device-luser-manage-test] quit
   ```
3. Configure the gRPC client.
   a. Prepare a PC and install the gRPC environment on the PC. For more information, see the user guide for the gRPC environment.
   b. Obtain the H3C proto definition file and uses the protocol buffer compiler to generate code of a specific language, for example, Java, Python, C/C++, or Go.
   c. Create a client application to call the generated code.
   d. Start the application to log in to the gRPC server.

Verifying the configuration

When an LLDP event occurs on the gRPC server, verify that the gRPC client receives the event.



Example: Configuring the gRPC dial-out mode

Network configuration

As shown in Figure 4, the device is connected to a collector. The collector uses port 50050.

Configure gRPC dial-out mode on the device so the device pushes the device capability information of its interface module to the collector at 10-second intervals.

Figure 4 Network diagram

Procedure

Configure IP addresses as required so the device and the collector can reach each other. (Details not shown.)

Enable the gRPC service.

```
<Device> system-view
[Device] grpc enable
```

Create a sensor group named **test**, and add sensor path **ifmgr/devicecapabilities/**.

```
[Device] telemetry
[Device-telemetry] sensor-group test
[Device-telemetry-sensor-group-test] sensor path ifmgr/devicecapabilities/
[Device-telemetry-sensor-group-test] quit
```

Create a destination group named **collector1**. Specify a collector that uses IPv4 address 192.168.2.1 and port number 50050.

```
[Device-telemetry] destination-group collector1
[Device-telemetry-destination-group-collector1] ipv4-address 192.168.2.1 port 50050
[Device-telemetry-destination-group-collector1] quit
```

Configure a subscription named **A** to bind sensor group **test** with destination group **collector1**. Set the data push interval to 10 seconds.

```
[Device-telemetry] subscription A
[Device-telemetry-subscription-A] sensor-group test sample-interval 10
[Device-telemetry-subscription-A] destination-group collector1
[Device-telemetry-subscription-A] quit
```

Verifying the configuration

Verify that the collector receives the device capability information of the interface module from the device at 10-second intervals. (Details not shown.)

Protocol buffer code

Protocol buffer code format

Google Protocol Buffers provide a flexible mechanism for serializing structured data. Different from XML code and JSON code, the protocol buffer code is binary and provides higher performance.

Table 3 compares a protocol buffer code format example and the corresponding JSON code format example.

Table 3 Protocol buffer and JSON code format examples

Protocol buffer code format example	Corresponding JSON code format example

Proto definition files

You can define data structures in a proto definition file. Then, you can compile the file with utility protoc to generate code in a programing language such as Java and C++. Using the generated code, you can develop an application for a collector to communicate with the device.

H3C provides proto definition files for both dial-in mode and dial-out mode.

Proto definition files for dial-in mode

Public proto definition files

Dial-in mode supports the following public proto definition files:

- **grpc_service.proto**—Defines the public RPC methods in dial-in mode.
- **gnmi.proto**—Defines the public RPC methods for gNMI operations.
- **gnmi_ext.proto**—Defines the extended message structures required by file **gnmi.proto**.

Files **gnmi.proto** and **gnmi_ext.proto** are from Google. For information about the download paths, see "Obtaining proto definition files."

The **grpc_service.proto** file is provided by H3C. The following are the contents of the file:

```
syntax = "proto2";
package grpc_service;
message GetJsonReply {   // Reply to the Get method
    required string result = 1;
}
message SubscribeReply { // Subscription result
    required string result = 1;
}
message ConfigReply {    // Configuration result
    required string result = 1;
}
message ReportEvent {    // Subscribed event
    required string token_id = 1;    // Login token_id
    required string stream_name = 2; // Event stream name
    required string event_name = 3;  // Event name
    required string json_text = 4;   // Subscription result, a JSON string
}
message GetReportRequest{ // Obtains the event subscription result
    required string token_id = 1; // Returns the token_id upon a successful login
}
message LoginRequest {  // Login request parameters
    required string user_name = 1; // Username
    required string password = 2; // Password
}
message LoginReply {  // Reply to a login request
    required string token_id = 1; // Returns the token_id upon a successful login
}
message LogoutRequest { // Logout parameter
    required string token_id = 1; // token_id
}
```

```
message LogoutReply { // Reply to a logout request
    required string result = 1; // Logout result
}
message SubscribeRequest { // Event stream name
    required string stream_name = 1;
}
message CliConfigArgs { // Sends a configuration command and the parameters to the device
    required int64 ReqId = 1; // Command request ID
    required string cli = 2;  // Command string
}
message CliConfigReply { // Reply to a configuration command execution request
    required int64 ResReqId = 1; // Request ID, which corresponds to that in CliConfigArgs
  required string output = 2;    // Output from the command
    required string errors = 3;  // Command execution result
}
message DisplayCmdArgs { // Sends a display command and the parameters to the device
    required int64 ReqId = 1; // Command request ID
    required string cli = 2;  // Command string
}
message DisplayCmdReply { // Reply to a display command execution request
    required int64 ResReqId =1; // Request ID, which corresponds to that in DisplayCmdArgs
    required string output = 2;  // Output from the command
    required string errors = 3;  // Command execution result
}
service GrpcService {    // gRPC methods
    rpc Login (LoginRequest) returns (LoginReply) {}      // Login method
    rpc Logout (LogoutRequest) returns (LogoutReply) {}   // Logout method
    rpc SubscribeByStreamName (SubscribeRequest) returns (SubscribeReply) {} // Event
subscription method
    rpc GetEventReport (GetReportRequest) returns (stream ReportEvent) {} // Method for
obtaining the subscribed event
    rpc CliConfig (CliConfigArgs)  returns (stream CliConfigReply) {} // Method for
executing a configuration command and returning the execution result
    rpc DisplayCmdTextOutput(DisplayCmdArgs)  returns(stream DisplayCmdReply) {} //
Method for executing a display command and returning the execution result
}
```

Proto definition files for service modules

The dial-in mode supports proto definition files for the following service modules: Device, Ifmgr, IPFW, LLDP, and Syslog.

The following are the contents of the **Device.proto** file, which defines the RPC methods for the Device module:

```
syntax = "proto2";
import "grpc_service.proto";
package  device;
message DeviceBase { // Structure for obtaining basic device information
    optional string HostName = 1;    // Device name
    optional string HostOid = 2;     // sysoid
    optional uint32 MaxChassisNum = 3;    // Maximum number of chassis
```

```
    optional uint32 MaxSlotNum = 4;  // Maximum number of slots
    optional string HostDescription = 5; // Device description
}
message DevicePhysicalEntities { // Structure for obtaining physical entity information
of the device
    message Entity {
        optional uint32 PhysicalIndex = 1;    // Entity index
        optional string VendorType = 2;       // Vendor type
        optional uint32 EntityClass = 3;      // Entity class
        optional string SoftwareRev = 4;      // Software version
        optional string SerialNumber = 5;     // Serial number
        optional string Model = 6;            // Model
    }
    repeated Entity entity = 1;
}
service DeviceService { // RPC methods
    rpc GetJsonDeviceBase(DeviceBase) returns (grpc_service.GetJsonReply) {} // Method
for obtaining basic device information
    rpc GetJsonDevicePhysicalEntities(DevicePhysicalEntities) returns
(grpc_service.GetJsonReply) {}   // Method for obtaining physical entity information of
the device
}
```

Proto definition files for dial-out mode

Public proto definition files

Dial-out mode supports the following public proto definition files:

- **grpc_dialout.proto**—Defines the public RPC methods in dial-out mode.
- **dial_out.proto**—Defines the subscription message formats for gNMI subscriptions in dial-out mode.
- **gnmi.proto**—Defines the public RPC methods in gNMI subscriptions.
- **gnmi_ext.proto**—Defines the extended message structures required by file **gnmi.proto**.

File **dial_out.proto** is from SONIC, and files **gnmi.proto** and **gnmi_ext.proto** are from Google. For information about the download paths, see "Obtaining proto definition files."

The **grpc_dialout.proto** file is provided by H3C. The following are the contents of the file:

```
syntax = "proto2";
package grpc_dialout;
message DeviceInfo{  // Pushed device information
    required string producerName = 1; // Vendor name
    required string deviceName = 2;   // Device name
    required string deviceModel = 3;  // Device model
}
message DialoutMsg{   // Format of the pushed data
    required DeviceInfo deviceMsg = 1; // Device information described by DeviceInfo
    required string sensorPath = 2; // Sensor path, which corresponds to xpath in NETCONF
    required string jsonData = 3;  // Sampled data, a JSON string
}
```

```
message DialoutResponse{  // Response from the collector. Reserved. The value is not
processed.
    required string response = 1;
}
service GRPCDialout {  // Data push method
    rpc Dialout(stream DialoutMsg) returns (DialoutResponse);
}
```

Obtaining proto definition files

To obtain proto files, contact H3C Support.

You can also download files **gnmi.proto**, **gnmi_ext.proto**, and **dial-out.proto** from the following websites respectively:

- https://github.com/openconfig/gnmi/tree/master/proto/gnmi/gnmi.proto
- https://github.com/openconfig/gnmi/tree/master/proto/gnmi_ext/gnmi_ext.proto
- https://github.com/Azure/sonic-telemetry/blob/master/proto/dial_out.proto

Example: Developing a gRPC collector-side application

Use a language (for example, C++) to develop a gRPC collector-side application on Linux to achieve the following goals:

- Collect device data by using Get, gNMI Capabilities, gNMI Get, or gNMI Subscribe operations in dial-in mode or by using dial-out mode.
- Send settings to the device by using gNMI Set or CLI operations in dial-in mode.

Prerequisites

1. Obtain proto definition files.
   - For Get operations in dial-in mode, obtain the **grpc_service.proto** file and proto definition files for service modules.
   - For gNMI operations in dial-in mode, obtain files **grpc_service.proto**, **gnmi.proto**, and **gnmi_ext.proto**.
   - For CLI operations in dial-in mode, obtain the **grpc_service.proto** file.
   - For non-gNMI subscriptions in dial-out mode, obtain the **grpc_dialout.proto** file.
   - For gNMI subscriptions in dial-out mode, obtain the **dial_out.proto**, **gnmi.proto**, and **gnmi_ext.proto** files.
2. Obtain utility protoc from https://github.com/google/protobuf/releases.
3. Obtain the protobuf plug-in for C++ (**protobuf-cpp**) from https://github.com/google/protobuf/releases.

Generating the C++ code for the proto definition files

Dial-in mode

Copy the required proto definition files to the current directory, for example, **grpc_service.proto** and **BufferMonitor.proto**.

```
$protoc --plugin=./grpc_cpp_plugin  --grpc_out=. --cpp_out=. *.proto
```

Dial-out mode

Copy proto definition file **grpc_dialout.proto** to the current directory.

```
$ protoc --plugin=./grpc_cpp_plugin  --grpc_out=.  --cpp_out=. *.proto
```

Developing the collector-side application (dial-in mode)

In dial-in mode, the application needs to provide the code to be run on the gRPC client.

The C++ code generated from the proto definition files already encapsulates the service classes. For the gRPC client to initiate RPC requests, you only need to call the RPC method in the application.

The application performs the following operations:

- Log in to obtain the token_id.
- Prepare parameters for the RPC method, use the service classes generated from the proto definition files to call the RPC method, and resolve the returned result.
- Log out.

Using Get operations

Service classes GrpcService and BufferMonitorService are used in this example.

To develop the collector-side application in dial-in mode:

1. Create a GrpcServiceTest class.

In the class, use the GrpcService::Stub class generated from grpc_service.proto. Implement login and logout with the Login and Logout methods generated from grpc_service.proto.

```
class GrpcServiceTest
{
public:
    /* Constructor functions */
    GrpcServiceTest(std::shared_ptr<Channel> channel):
GrpcServiceStub(GrpcService::NewStub(channel))  {}

    /* Member functions */
    int Login(const std::string& username, const std::string& password);
    void Logout();
    void listen();
Status listen(const std::string& command);

    /* Member variable */
    std::string token;

private:
    std::unique_ptr<GrpcService::Stub> GrpcServiceStub;  // Use the
GrpcService::Stub class generated from grpc_service.proto.
};
```

2. Customize the Login method.

Call the Login method of the GrpcService::Stub class to allow a user who provides the correct the username and password to log in.

```
int GrpcServiceTest::Login(const std::string& username, const std::string& password)
{
    LoginRequest request;   // Username and password.
    request.set_user_name(username);
```

```
    request.set_password(password);

LoginReply reply;
ClientContext context;

    // Call the Login method.
    Status status = GrpcServiceStub->Login(&context, request, &reply);
    if (status.ok())
    {
        std::cout << "login ok!" << std::endl;
        std::cout <<"token id is :" << reply.token_id() << std::endl;
        token = reply.token_id();  // The login succeeds. The token is obtained.
        return 0;
    }
    else{
        std::cout << status.error_code() << ": " << status.error_message()
                  << ". Login failed!" << std::endl;
        return -1;
    }
}
```

3. Initiate an RPC request to the device. In this example, the application subscribes to interface packet drop events.

```
rpc SubscribePortQueDropEvent(PortQueDropEvent) returns
(grpc_service.SubscribeReply) {}
```

4. Create the BufMon_GrpcClient class to encapsulate the RPC method.

Use the BufferMonitorService::Stub class generated from BufferMonitor.proto to call the RPC method.

```
class BufMon_GrpcClient
{
public:
    BufMon_GrpcClient(std::shared_ptr<Channel> channel):
mStub(BufferMonitorService::NewStub(channel))
    {}

    std::string BufMon_Sub_AllEvent(std::string token);
    std::string BufMon_Sub_BoardEvent(std::string token);
    std::string BufMon_Sub_PortOverrunEvent(std::string token);
    std::string BufMon_Sub_PortDropEvent(std::string token);

    /* Get entries */
    std::string BufMon_Sub_GetStatistics(std::string token);
    std::string BufMon_Sub_GetGlobalCfg(std::string token);
    std::string BufMon_Sub_GetBoardCfg(std::string token);
    std::string BufMon_Sub_GetNodeQueCfg(std::string token);
    std::string BufMon_Sub_GetPortQueCfg(std::string token);

private:
   std::unique_ptr<BufferMonitorService::Stub> mStub; // Use the class generated
from BufferMonitor.proto.
```

```
};
```

5. Use std::string BufMon_Sub_PortDropEvent(std::string token) to implement interface packet drop event subscription.

```
std::string BufMon_GrpcClient::BufMon_Sub_PortDropEvent(std::string token)
{
    std::cout << "-------BufMon_Sub_PortDropEvent-------- " << std::endl;

    PortQueDropEvent stNodeEvent;
    PortQueDropEvent_PortQueDrop* pstParam = stNodeEvent.add_portquedrop();

    UINT uiIfIndex = 0;
    UINT uiQueIdx = 0;
    UINT uiAlarmType = 0;

    std::cout<<"Please input interface queue info : ifIndex queIdx alarmtype " <<
std::endl;
    cout<<"alarmtype : 1 for ingress; 2 for egress; 3 for port headroom"<<endl;

    std::cin>>uiIfIndex>>uiQueIdx>>uiAlarmType; // Set the subscription parameters
and interface index.
    pstParam->set_ifindex(uiIfIndex);
    pstParam->set_queindex(uiQueIdx);
    pstParam->set_alarmtype(uiAlarmType);

    ClientContext context;

    /* Token needs to be added to context */ // Set the token_id to be returned after
a successful login
    std::string key = "token_id";
    std::string value = token;
    context.AddMetadata(key, value);

    SubscribeReply reply;
    Status status = mStub->SubscribePortQueDropEvent(&context,stNodeEvent,&reply);
// Call the RPC method.

    return reply.result();
}
```

6. Use a loop to listen for event reports.

Implement this method in the GrpcServiceTest class.

```
void GrpcServiceTest::listen()
{
    GetReportRequest reportRequest;
    ClientContext context;
    ReportEvent reportedEvent;

    /* Add the token to the request */
    reportRequest.set_token_id(token);
```

```
    std::unique_ptr< ClientReader< ReportEvent>>
reader(GrpcServiceStub->GetEventReport(&context, reportRequest)); // Use
GetEventReport (which is generated from grpc_service.proto) to obtain event
information.

    std::string streamName;
    std::string eventName;
    std::string jsonText;
    std::string token;

    JsonFormatTool jsonTool;

    std::cout << "Listen to server for Event" << std::endl;
    while(reader->Read(&reportedEvent) ) // Read the received event report.
    {
        streamName = reportedEvent.stream_name();
        eventName = reportedEvent.event_name();
        jsonText = reportedEvent.json_text();
        token = reportedEvent.token_id();

          std::cout << "/***********EVENT COME**************/" << std::endl;
        std::cout << "TOKEN: " << token << std::endl;
        std::cout << "StreamName: "<< streamName << std::endl;
        std::cout << "EventName: " << eventName << std::endl;
        std::cout << "JsonText without format: " << std::endl << jsonText << std::endl;
        std::cout << std::endl;
        std::cout << "JsonText Formated: " << jsonTool.formatJson(jsonText) <<
std::endl;
        std::cout << std::endl;
    }

    Status status = reader->Finish();
    std::cout << "Status Message:" << status.error_message() << "ERROR code :" <<
status.error_code();
}  // Login and RPC request finished.
```

7. Call the Logout method to log out.

```
void GrpcServiceTest:: Logout ()
{
    LogoutRequest request;
    request.set_token_id(token);
    LogoutReply reply;
    ClientContext context;
    Status status = mStub->Logout(&context, request, &reply);
std::cout << "Logout! :" << reply.result() << std::endl;
}
```

Using gNMI Capabilities operations

1. Create a GrpcServiceTest class.

   See step 1 in "Using Get operations."

2. Customize the Login method.

   See step 2 in "Using Get operations."

3. Initiate an RPC request to the device.

```
rpc Capabilities(CapabilityRequest) returns (CapabilityResponse);
```

4. Create the gnmi_client class to encapsulate the RPC method.

```
class gnmi_client
{
public:
    explicit gnmi_client(const std::string &address,const std::string &tokenId);

    bool TestCapabilities();
    bool TestGet();
    bool TestSet();
    bool TestSubscribePool();
    bool TestSubscribeOnce();
    bool TestSubscribeStream();
    bool TestSubscribeStreamWithAlias();

private:
    void PrintCapabilityResponse(const gnmi::CapabilityResponse &response);
    void PrintGetResponse(const gnmi::GetResponse &response);
    void PrintSubscribeResponse(const gnmi::SubscribeResponse &response);
    void PrintSubscribeRequest(const gnmi::SubscribeRequest &request);
    void PrintGetRequest(const gnmi::GetRequest &request);
    void PrintSetRequest(const gnmi::SetRequest &request);

    void FillGetRequest(gnmi::GetRequest &request);
    void FillSetRequest(gnmi::SetRequest &request);
    void FillSubscribeRequestByOnce(gnmi::SubscribeRequest &request);
    void FillSubscribeRequestByPool(gnmi::SubscribeRequest &request);
    void FillSubscribeRequestByStream(gnmi::SubscribeRequest &request);
    void FillSubscribePool(gnmi::SubscribeRequest &request);
    void FillSubscribeAlias(gnmi::SubscribeRequest &request);

private:
    std::unique_ptr<gnmi::gNMI::Stub> mStubGnmiService;
    std::string mTokenID;
};
```

5. Use the TestCapabilities() method to obtain the capabilities.

```
bool gnmi_client::TestCapabilities()
{
    CapabilityRequest request;
    CapabilityResponse response;
    ClientContext context;

  context.AddMetadata("token_id", mTokenID);
```

```
    std::cout << std::endl << "CapabilitiesRequest => " << std::endl;
    Status ret = mStubGnmiService->Capabilities(&context,request,&response);

    if( StatusCode::OK != ret.error_code() )
    {
        cout << "TestCapabilities ErrorMessage:" << ret.error_message() << endl;
        return false;
    }
    else
    {
        PrintCapabilityResponse(response);
        return true;
    }
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Get operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."
2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   ```
   rpc Get(GetRequest) returns (GetResponse);
   ```
4. Create the gnmi_client class to encapsulate the RPC method.
   See step 4 in "Using gNMI Capabilities operations."
5. Use the TestGet() method to obtain the Device/Base/HostName.
   ```
   bool gnmi_client::TestGet()
   {
     GetRequest request;
     FillGetRequest(request);
     PrintGetRequest(request);
     GetResponse response;
     ClientContext context;

     context.AddMetadata("token_id", mTokenID);

     Status ret = mStubGnmiService->Get(&context,request,&response);

     if( StatusCode::OK != ret.error_code() )
     {
       cout << "TestGet ErrorMessage:" << ret.error_message() << endl;
       return false;
     }
     else
     {
       PrintGetResponse(response);
       return true;
   ```

```
  }
}

void gnmi_client::FillGetRequest(gnmi::GetRequest &request)
{
    auto prefix = request.mutable_prefix();
    auto pathelem01 = prefix->add_elem();
    pathelem01->set_name("Device");

    auto path1 = request.add_path();
    auto pathelem02 = path1->add_elem();
    pathelem02->set_name("Base");
    auto pathelem03 = path1->add_elem();
    pathelem03->set_name("HostName");
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Set operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."
2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   This example uses the Device module.
   ```
   rpc Set(SetRequest) returns (SetResponse)
   ```
4. Create a gNMITest class to encapsulate the RPC method.
   Use the gNMI::Stub class that is automatically created by gnmi.proto to call the RPC method.
   ```
   class gNMITest
   {
   public:
   gNMITest(std::shared_ptr<Channel> channel, const std::string tokenId ):

   mStubGrpcService(GrpcService::NewStub(channel)),

   mStubgNMIService(gNMI::NewStub(channel)),
                                                mTokenID(tokenId ){}
        SetResponse TestSetResponseInformation(SetRequest &request, const std::string
   tokenId);
   /*---delete: Device/Base/HostName. Restore the default for HostName -----------*/
   SetResponse DeleteDeviceBaseHostName();      /* delete: Device Base/HostName*/

   /* update: Device/Base/HostName, string_val("string_hostname") */
   SetResponse UpdateDeviceBaseHostNameStringVal();

   /* replace: Device/Base/HostName, string_val("string_hostname") */
   REPL_001 SetResponse ReplaceDeviceBaseHostNameStringVal();
   ```

```
private:
std::unique_ptr<GrpcService::Stub> mStubGrpcService;
std::unique_ptr<gNMI::Stub> mStubgNMIService;
std::string mTokenID;
};
```

5. Use customized methods to perform gNMI Set operations on service data, for example, on the Device module.

```
// Call the Set method to implement communication between client and server and get
the response.
SetResponse gNMITest::TestSetResponseInformation(SetRequest &request, const
std::string tokenId)
{
SetResponse reply;
ClientContext context;
context.AddMetadata("token_id", tokenId);

/* Call the Set method */
Status ret = mStubgNMIService->Set(&context,request,&reply);
if( StatusCode::OK != ret.error_code())
{
std::cout<<"error: "<<ret.error_message()<<std::endl;
}
return reply;
}
// Delete operation
SetResponse gNMITest:: DeleteDeviceBaseHostName ()        /* prefix == Device/Base
*/
{
SetRequest  request;
/* SetRequest->prefix */
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->delete */
Path        *path02 = request.add_delete_();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");
/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
}
// Update operation
SetResponse gNMITest::UpdateDeviceBaseHostNameStringVal()
{
SetRequest  request;

/* SetRequest->prefix */
```

```
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->update */
Update      *update01 = request.add_update();
Path        *path02 = update01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");

TypedValue  *typevalue01 = update01->mutable_val();
typevalue01->set_string_val("string_hostname");

/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
}
// Replace operation
SetResponse gNMITest::ReplaceDeviceBaseHostNameStringVal()
{
SetRequest  request;

/* SetRequest->prefix */
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->replace */
Update      *replace01 = request.add_replace();
Path        *path02 = replace01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");

TypedValue  *typevalue01 = replace01->mutable_val();
typevalue01->set_string_val("string_hostname");

/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Subscribe operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."

2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   ```
   rpc Subscribe(stream SubscribeRequest) returns (stream SubscribeResponse);
   ```
4. Create the gnmi_client class to encapsulate the RPC method.
   See step 4 in "Using gNMI Capabilities operations."
5. Create a subscribe method.

```
void gnmi_client::FillSubscribeRequestByOnce(gnmi::SubscribeRequest &request)
{
  auto subscribeList = request.mutable_subscribe();

  auto prefix = subscribeList->mutable_prefix();
  auto pathelem01 = prefix->add_elem();
  pathelem01->set_name("LLDP");

  auto subscribe = subscribeList->add_subscription();

  auto path = subscribe->mutable_path();
  auto pathelem02 = path->add_elem();
  pathelem02->set_name("NeighborEvent");

  auto pathelem03 = path->add_elem();
  pathelem03->set_name("Neighbor");
  (*pathelem03->mutable_key())["IfName"] = "xxx";

    subscribeList->set_mode(::gnmi::SubscriptionList_Mode_ONCE);
    subscribeList->set_encoding(::gnmi::JSON);
}

void gnmi_client::FillSubscribeRequestByPool(gnmi::SubscribeRequest &request)
{
    auto subscribeList =  request.mutable_subscribe();

    auto prefix = subscribeList->mutable_prefix();
    auto pathelem01 = prefix->add_elem();
    pathelem01->set_name("Device");

    auto subscribe = subscribeList->add_subscription();

    auto path = subscribe->mutable_path();
    auto pathelem02 = path->add_elem();
    pathelem02->set_name("CPUs");
    auto pathelem03 = path->add_elem();
    pathelem03->set_name("CPU");
    auto pathelem04 = path->add_elem();
    pathelem04->set_name("CPUUsage");

    subscribeList->set_mode(::gnmi::SubscriptionList_Mode_POLL);
```

```
    subscribeList->set_encoding(::gnmi::JSON);
}

void gnmi_client::FillSubscribeRequestByStream(gnmi::SubscribeRequest &request)
{
     auto subscribeList =  request.mutable_subscribe();

     auto prefix = subscribeList->mutable_prefix();
     auto pathelem01 = prefix->add_elem();
     pathelem01->set_name("Diagnostic");

     auto subscribe = subscribeList->add_subscription();

     auto path = subscribe->mutable_path();
     auto pathelem02 = path->add_elem();
     pathelem02->set_name("CPUEvent");
     auto pathelem03 = path->add_elem();
     pathelem03->set_name("CPU");
     (*pathelem03->mutable_key())["Chassis#condition"] = "equal:1";
     subscribe->set_mode(::gnmi::ON_CHANGE);
     subscribe->set_sample_interval(1000);
     subscribe->set_suppress_redundant(false);
     subscribe->set_heartbeat_interval(1000);

     subscribeList->set_mode(::gnmi::SubscriptionList_Mode_STREAM);
     subscribeList->set_encoding(::gnmi::JSON);
}

void gnmi_client::FillSubscribeAlias(gnmi::SubscribeRequest &request)
{
    auto aliases = request.mutable_aliases();
    auto alias = aliases->add_alias();

    auto path = alias->mutable_path();
    auto pathelem01 = path->add_elem();
    pathelem01->set_name("Device");
    auto pathelem02 = path->add_elem();
    pathelem02->set_name("CPUs");
    auto pathelem03 = path->add_elem();
    pathelem03->set_name("CPU");
    auto pathelem04 = path->add_elem();
    pathelem04->set_name("CPUUsage");

    alias->set_alias("#cpu_usage");
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using CLI operations

1. Create a GrpcServiceTest class.

   See step 1 in "Using Get operations."
2. Customize the Login method.

   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.

   This example uses the CliConfig method in file **grpc_service.proto**.

   ```
   rpc CliConfig (CliConfigArgs)  returns (stream CliConfigReply) {}
   ```
4. Use the GrpcServiceTest class to encapsulate the RPC method in the same way you do for Get operations.
5. Use a customized method to support CliConfig operations.

   ```
   // Make a thread to listen to the sever and get messages
   Status GrpcServiceTest::listen(const std::string& command)
   {
   CliConfigArgs reportRequest;
   ClientContext context;
   CliConfigReply reportedEvent;
   std::string key = "token_id";
   std::string value = token;
   context.AddMetadata(key, value);
   /* Add token to request */
   reportRequest.set_reqid(12345678);
   reportRequest.set_cli(command);

   std::unique_ptr< ClientReader< CliConfigReply>> reader(mStub->CliConfig(&context,
   reportRequest));

   std::string streamName;
   std::string output;
   int64 resreqid;

   std::cout << "Command result" << std::endl;
   while( reader->Read(&reportedEvent) )
   {
   streamName = reportedEvent.errors();
   output = reportedEvent.output();
   resreqid = reportedEvent.resreqid();
   std::cout << "resreqid: "<< resreqid << std::endl;
   std::cout << "errors: "<< streamName << std::endl;
   std::cout << "output: \n"<< output << "\n"<< std::endl;
   }
   Status status = reader->Finish();
   return status;
   }
   ```
6. Use a loop in the main function to wait for commands.

   Use the GrpcServiceTest class.

   ```
   int main(int argc, char *argv[])
   {
   ```

```
const char *cmd;
unsigned int i = 0;
unsigned int cycle = 0;

if (4 == argc)
{
g_server_address = argv[1];
g_username = argv[2];
g_password = argv[3];
std::cout << "server_address: " << g_server_address <<std::endl;
std::cout << "username: " << g_username << " " << "password: " << g_password <<
std::endl;
auto channel =
grpc::CreateChannel(g_server_address,grpc::InsecureChannelCredentials());
 // 1. Log in
GrpcServiceTest reporter(channel);
if(0 != reporter.Login(g_username, g_password))
        {
            return 0;
        }
        while(1)
        {// 2. Read a command and execute the command
                std::cout<<"\n\nPlease Input Command:\n";
                getline(std::cin,g_command);          // Read a command
                Status status = reporter.listen(g_command);
                if (!status.ok())
               {
                   std::cout << status.error_code() << ": " << status.error_message()
<< std::endl;
                    break;
               }
        }
    }
   std::cout<<"Complete exec Command."<<std::endl;
   return 0;
}
```

7. Call the Logout method to log out.

See step 7 in "Using Get operations."

Developing the collector-side application (dial-out mode)

In dial-out mode, the application needs to provide the gRPC server code so the collector can receive and resolve data obtained from the device.

The application performs the following operations:

- Inherit the automatically generated GRPCDialout::Service class, reload the automatically generated RPC Dialout service, and resolve the fields.
- Register the RPC service with the specified listening port.

To develop the collector-side application in dial-out mode:

1. Inherit and overload RPC service Dialout.

   # Create class DialoutTest and inherit GRPCDialout::Service.

```
class DialoutTest final : public GRPCDialout::Service { // Overload the automatically generated abstract class.
    Status Dialout(ServerContext* context, ServerReader< DialoutMsg>* reader, DialoutResponse* response) override; // Implement RPC method Dialout.
};
```

2. Register the DialoutTest service as a gRPC service and specify the listening port.

```
using grpc::Server;
using grpc::ServerBuilder;
std::string server_address("0.0.0.0:60057"); // Specify the address and port to listen to.
DialoutTest dialout_test; // Define the object declared in step 1.
ServerBuilder builder;
builder.AddListeningPort(server_address, grpc::InsecureServerCredentials());// Add the listening port.
builder.RegisterService(&dialout_test); // Register the service.
std::unique_ptr<Server> server(builder.BuildAndStart()); // Start the service.
server->Wait();
```

3. Implement the Dialout method and data resolution.

```
Status DialoutTest::Dialout(ServerContext* context, ServerReader< DialoutMsg>* reader, DialoutResponse* response)
{
        DialoutMsg msg;

        while( reader->Read(&msg))
        {
            const DeviceInfo &device_msg = msg.devicemsg();
            std::cout<< "Producer-Name: " << device_msg.producername() << std::endl;
            std::cout<< "Device-Name: " << device_msg.devicename() << std::endl;
            std::cout<< "Device-Model: " << device_msg.devicemodel() << std::endl;
            std::cout<<"Sensor-Path: " << msg.sensorpath()<<std::endl;
            std::cout<<"Json-Data: " << msg.jsondata()<<std::endl;
            std::cout<<std::endl;
        }
        response->set_response("test");

        return Status::OK;
}
```

4. After obtaining the DialoutMsg object (generated from the proto definition file) through the Read method, call the method to obtain the field values.

Appendix: Methods and attributes for gNMI operations

gNMI operations are intended for data tables and event tables.

- Some data tables are periodically reported and some data tables are reported only when triggered. The latter data tables are not supported in the current software version.
- All event tables are reported only when triggered.

Methods for adding columns in gNMI operations

Table 4 describes the methods for adding columns in gNMI operations.

Table 4 Methods for adding columns in gNMI operations

Request description	Sample request	Sample client-side code

Set a column of the key.
For example:
ifTypeExt=*colvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"ifTypeExt"
	value:"*colvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["ifTypeExt"] = "*colvalue*";

Set an attribute for a column of the key.
For example, set the attr attribute of ifTypeExt:
attr=*attrvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"ifTypeExt#attr"
	value:"*attrvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["ifTypeExt#attr"] = "*attrvalue*";

Set a column in a group of the key.
For example, set the Upper column of the Broadcast group:
Upper=*colvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"Broadcast:Upper"
	value:"*colvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["Broadcast:Upper"] = "*colvalue*";

Set an attribute for a column in a group of the key.
For example, set the attr attribute of the Upper column of the Broadcast group:
attr=*attrvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"Broadcast:Upper#attr"
	value:"*attrvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["Broadcast:Upper#attr"] = "*attrvalue*";

Set an attribute of a column through the key:
For example, set the attr attribute of Interface:
attr=*attrvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["#a

Request description	Sample request	Sample client-side code
	name:"#attr" value:"*attrvalue*" > > >	ttr"] = "*attrvalue*";

Set a column or column attribute in JSON:
For example:
Set Upper to *colvalue* and set the attr attribute of Upper to *attrvalue*.
	{
	"Upper": {
	"#text": "*colvalue*",
	"@#attr": "*attrvalue*"
	}
	}
		{
		"Upper": {
		"#text": "*colvalue*",
		"@#attr": "*attrvalue*"
		}
		}

The YANG files for different YANG models might have a top-level node with the same name. To specify the top-level node in the YANG file for a particular YANG model, add the YANG model name before the top-level node name. If you do not add the YANG model name, the top-level node in the first YANG file is specified.
For example, add oc-if before node interfaces to specify the interfaces node in the YANG file for OpenConfig.
	path:
	<
	elem:
	<
	name:"oc-if:interfaces"
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("oc-if:interfaces");

gNMI Get operation attributes

gNMI Get operations support the following attributes:

- **regExp**—Regular expression.

  To implement a complex filtering with characters, you can add a **regExp** attribute for a specific column.

  The following example obtains the interface descriptions that contain only characters in upper case:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("Ifmgr");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("Interfaces");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Interface");
 auto pathelem04 = path1->add_elem();
 pathelem04->set_name("Description");
 (*pathelem04->mutable_key())["#regExp"] = "^[A-Z]*$";
```

- **match**—Conditional match.

  Table 5 describes the conditional match operators.

Table 5 Conditional match operators

Operation	Operator	Description
More than	match="more:*value*"	More than the specified value. The supported data types include date, digit, and character string.
Less than	match="less:*value*"	Less than the specified value. The supported data types include date, digit, and character string.
Not less than	match="notLess:*value*"	Not less than the specified *value*. The supported data types include date, digit, and character string.
Not more than	match="notMore:*value*"	Not more than the specified *value*. The supported data types include date, digit, and character string.
Equal to	match="equal:*value*"	Equal to the specified *value*. The supported data types include date, digit, character string, OID, and BOOL.
Not equal to	match="notEqual:*value*"	Not equal to the specified *value*. The supported data types include date, digit, character string, OID, and BOOL.
Include	match="include:*string*"	Includes the specified *string*. The supported data types include only character string.
Not include	match="exclude:*string*"	Excludes the specified *string*. The supported data types include only character string.
Start with	match="startWith:*string*"	Starts with the specified *string*. The supported data types include character string and OID.
End with	match="endWith:*string*"	Ends with the specified *string*. The supported data types include only character string.

The following example obtains extension information about the entity whose CPU usage is more than 50%:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("Device");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("ExtPhysicalEntities");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Entity");
 auto pathelem04 = path1->add_elem();
 pathelem04->set_name("CpuUsage");
 (*pathelem04->mutable_key())["#match"] = "more:50";
```

- **valuetype**—Attribute value type.

  When obtaining interface information, the device cannot identify whether an integer value for the IfIndex or vrfindex column represents an interface name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

  The **valuetype** attribute has the following values:

Value	Description
name	The column is carrying a name.
index	The column is carrying an index.
auto	Default value. The device uses the value of the column as a name for

Value	Description
	interface matching. If no match is found, the device uses the value as an index for interface matching.

The following example sets the valuetype attribute to index and set the index to 1 for IfIndex:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("VLAN");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("TrunkInterfaces");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Interface");
(*pathelem03->mutable_key())["IfIndex"] = "1";
(*pathelem03->mutable_key())["IfIndex#valuetype"] = "index";
```

- **count**—Specifies the data entry quantity.

  The example sets the count attribute:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("Syslog");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("Logs");
(*pathelem03->mutable_key())["count"] = "5";
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Log");
(*pathelem03->mutable_key())["Index"] = "10";
```

- Value filtering

  You can specify a value for a column in a table to implement full match filtering. If you specify values for multiple columns, the system returns the data that matches all the specified values.

  The following example obtains information about interface whose IfIndex is 1.

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("VLAN");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("TrunkInterfaces");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Interface");
(*pathelem03->mutable_key())["IfIndex"] = "1";
```

gNMI Set operation attributes

gNMI Set operations support the following attributes:

- **incremental**—Adds configuration data to a column without affecting the original data. This attribute applies to a list column such as the vlan permitlist column.

This example adds VLANs 1 through 10 to an untagged VLAN list that has untagged VLANs 12 through 15.

```
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("VLAN");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("HybridInterfaces");

Update  *Update01 = request.add_update();
Path        *path02 = Update01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("Interface");
(*pathelem03->mutable_key())["IfName"] = "262";
(*pathelem03->mutable_key())["UntaggedVlanList#incremental"] = "true";
(*pathelem03->mutable_key())["UntaggedVlanList"] = "1-10";
```

- **valuetype**—Attribute value type.

  When configuring an interface, the device cannot identify whether an integer value for the IfIndex or vrfindex column represents an interface name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

  The **valuetype** attribute has the following values:

Value	Description
name	The column is carrying a name.
index	The column is carrying an index.
auto	Default value. The device uses the value of the column as a name for interface matching. If no match is found, the device uses the value as an index for interface matching.

  The following example sets the valuetype attribute to index and set the index to 1 for IfIndex:

```
    Path    *path01 = request.mutable_prefix();
    PathElem*pathelem01 = path01->add_elem();
    pathelem01->set_name("VLAN");
    PathElem*pathelem02 = path01->add_elem();
    pathelem02->set_name("TrunkInterfaces");

    /* SetRequest->delete */
    Path    *path02 = request.add_delete_();
    PathElem*pathelem04 = path02->add_elem();
    pathelem04->set_name("Interface ");
(*pathelem04->mutable_key())["IfIndex"] = "1";
(*pathelem04->mutable_key())["IfIndex#valuetype"] = "index";
```

gNMI Subscribe operation attributes

gNMI Subscribe operations support the following attributes:

- All gNMI Get operation attributes. See "gNMI Get operation attributes."

  These attributes are used for subscription to periodically reported data tables.

- **condition**—Data pushing condition.

  This attribute is used for event table subscription. Values for this attribute are as follows:

  - **more**—More than.

- **less**—Less than.
- **notLess**—Not less than.
- **notMore**—Not more than.
- **equal**—Equal to.
- **notEqual**—Not equal to.
- **include**—Include.
- **exclude**—Not include.
- **startWith**—Start with.
- **endWith**—End with.

The following example monitors LLDP events:

```
auto prefix = subscribeList->mutable_prefix();
auto pathelem01 = prefix->add_elem();
pathelem01->set_name("LLDP");

auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
auto pathelem02 = path->add_elem();
pathelem02->set_name("NeighborEvent");
auto pathelem03 = path->add_elem();
pathelem03->set_name("Neighbor");
(*pathelem03->mutable_key())["IfName"] = "GigabitEthernet1/0/1";
(*pathelem03->mutable_key())["IfName#condition"] = "equal";
```

- **match**—Conditional match.

  This attribute is used for data table subscription.

  The matching object can be a fixed value or another column. The latter supports only data tables that are reported only when triggered.

  Table 5 describes the conditional match operators for matching a fixed value. Attribute values for matching another column are as follows:

  - **refMore**—More than.
  - **refLess**—Less than.
  - **refNotLess**—Not less than.
  - **refNotMore**—Not more than.
  - **refEqual**—Equal to.
  - **refNotEqual**—Not equal to.

  In the following example, a report is triggered only if the current-usage column has a greater value than the alarm-threshold column:

```
auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
auto pathelem02 = path->add_elem();
pathelem02->set_name("queue");
auto pathelem03 = path->add_elem();
pathelem03->set_name("state");
(*pathelem03->mutable_key())["current-usage#match"] = "refMore:alarm-threshold";
```

- **select**—Reports certain columns in a data table that is reported only when triggered

  The following example reports only the current-usage column and the available-usage column:

```
auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
```

```
auto pathelem02 = path->add_elem();
pathelem02->set_name("queue");
auto pathelem03 = path->add_elem();
pathelem03->set_name("state");
(*pathelem03->mutable_key())["current-usage#select"] = "";
(*pathelem03->mutable_key())["available-usage#select"] = "";
```

H3C Network Technology Acronyms

A B C D E F G H I K L M N O P Q R S T U V W X Z

10GE	Ten-GigabitEthernet
1DM	One-way Delay Measurement
3DES	Triple Data Encryption Standard

EUI-64	64-bit Extended Unique Identifier
EVB	Edge Virtual Bridging
Event MIB	Event Management Information Base
EVFP	Exchange Virtual Fabrics Parameter
EVI	Ethernet Virtual Interconnect
EVPN	Ethernet Virtual Private Network
Extended-MAM	Extended Maximum Allocation Model
F	Return
FA	Foreign Agent
FA	Foreign-AC
FAC	Feature Access Code
FAS	Frame Alignment Signal
FC	Forwarding Class
FC	Fibre Channel
FC	Feasibility Condition
FCF	FCoE Forwarder
FCM	Fast Connect Modem
FCoE	Fibre Channel over Ethernet
FCPS	FC Port Security
FCS	Fabric Configuration Server
FCS	Frame Check Sequence
FD	Feasible Distance
FDB	Forwarding Database

FDMI	Fabric Device Management Interface
FE	Fast Ethernet
FEAC	Far End Alarm and Control signal
FEC	Forward Error Correction
FEC	Forwarding Equivalence Class
FECN	Forward Explicit Congestion Notification
FEP	Front End Processor
FF	Fixed-Filter
FFD	Fast Failure Detection
FFT	Fast Fourier Transform
FG	Forwarding Group
FHR	First Hop Router
FIB	Forwarding Information Base
FIFO	First In First Out
FIFO	First In First Out Queuing
FIP	FCoE Initialization Protocol
FIP Snooping	FCoE Initialization Protocol Snooping
FIPS	Federal Information Processing Standards
Flowspec	Flow Specification
FNG	Fault Notification Generator
FP	Forwarding Profile
FPGA	Field Programmable Gate Array
FPMA	Fabric Provided MAC Address
FQ	Fair Queuing
FQDN	Fully Qualified Domain Name
FR	Frame Relay
FRR	Fast Reroute
FRTP	Frame Relay Traffic Policing
FRTS	Frame Relay Traffic Shaping
FRU	Field Replaceable Unit
FS	Forced Switch
FS	Feasible Successor
FSK	Frequency Shift Keying
FSPF	Fabric Shortest Path First
FT	Fault Tolerance
FT	Fast BSS Transition
FTN	FEC to NHLFE map
FTP	File Transfer Protocol
FXO	Foreign Exchange Office
FXS	Foreign Exchange Station

G	Return
GAL	G-ACh Label
GARP	Generic Attribute Registration Protocol
GAS	Generic Advertisement Service
GDOI	Group Domain of Interpretation
GE	Gigabit Ethernet
GI	Guard Interval
GK	GateKeeper
GLB	Global Load Balance
GM	Group Member
GM	Grandmaster Clock
GMK	Group Master Key
GNE	Gateway Network Element
GNS	Get Nearest Server
GOLD	Generic OnLine Diagnostics
GPS	Global Positioning System
GR	Graceful Restart
GRE	Generic Routing Encapsulation
Group Domain VPN	Group Domain Virtual Private Network
gRPC	Google Remote Procedure Call
GSMPv3	General Switch Management Protocol Version 3
GTC	Generic Token Card
GTK	Group Temporal Key
GTP	GPRS Tunneling Protocol
GTP-U	GPRS Tunneling Protocol User
GTS	Generic Traffic Shaping
GTSM	Generalized TTL Security Mechanism
GVRP	GARP VLAN Registration Protocol
GW	Gateway
GWMP	Gateway Message Protocol
H	Return
HA	Home-AC
HA	High Availability
HA	Home Agent
HABP	HW Bypass Protocol
HBA	Host Bus Adapter
HDB3	High-density bipolar 3
HDLC	High-level Data Link Control
HDSL	High-speed Digital Subscriber Line

HESSID	Homogenous Extended Service Set IDentifier
HGMP	HW Group Management Protocol
HGMPv2	HW Group Management Protocol version 2
HMAC	Hash-based Message Authentication Code
HoPE	Hierarchy of PE
HoVPN	Hierarchy of VPN
HQoS	Hierarchical Quality of Service
HS	High-performance Switch
HTTP	Hypertext Transfer Protocol
HTTPS	Hypertext Transfer Protocol Secure
H-VPLS	Hierarchical VPLS
HWTACACS	HW Terminal Access Controller Access Control System
I	Return
IA	Identity Association
IACTP	Inter Access Controller Tunneling Protocol
IAD	Integrated Access Device
IANA	Internet Assigned Numbers Authority
IBGP	Internal Border Gateway Protocol
ICANN	Internet Corporation for Assigned Names and Numbers
ICMP	Internet Control Message Protocol
ICMPv6	Internet Control Message Protocol for IPv6
ICP	IMA Control Protocol
ICPIF	Calculated Planning Impairment Factor
ICRQ	Incoming Call Request
IDN	Integrated Digital Network
IDS	Intrusion Detection System
IE	Information Element
IE	Interconnect Element
IEEE	Institute of Electrical and Electronics Engineers
IETF	Internet Engineering Task Force
IGMP	Internet Group Management Protocol
IGMP Snooping	Internet Group Management Protocol Snooping
IGP	Interior Gateway Protocol
IGTK	Integrity Group Temporal Key
IIH	Intermediate System-to-Intermediate System Hello
IKE	Internet Key Exchange
IKEv2	Internet Key Exchange Version 2
ILM	Incoming Label Map
ILS	Internet Locator Service

IM	Instant Messaging
IMA	Inverse Multiplexing for ATM
IMAP	Internet Mail Access Protocol
iMC	Intelligent Management Center
IMSI	International Mobile Subscriber Identification Number
InARP	Inverse Address Resolution Protocol
IND	Inverse Neighbor Discovery
INT	In-band Network Telemetry
IntServ	Integrated Service
IPC	Inter-process Communication
IPE	Image Package Envelope
IPHC	IP Header Compression
IPL	Intra-Portal Link
IPN	IGTK Packet Number
IPng	IP Next Generation
IPoA	IP over ATM
IPoEoA	IP over Ethernet over ATM
IPP	Intra-Portal Port
IPS	Intrusion Prevention System
IPsec	IP Security
IPTA	IP Terminal Access
IPv6	Internet Protocol version 6
IPv6 MBGP	IPv6 Multicast BGP
IPv6 ND	IPv6 Neighbor Discovery
IPv6 PIM	IPv6 Protocol Independent Multicast
IPv6 PIM Snooping	IPv6 Protocol Independent Multicast Snooping
IPX	Internetwork Packet Exchange
IRB	Integrated Bridging and Routing
IRB	Integrated Routing and Bridging
IRB	Integrated Routing Bridging and Bridging Routing
IRDP	ICMP Router Discovery Protocol
IRF	Intelligent Resilient Framework
IS	Intermediate System
ISAKMP	Internet Security Association and Key Management Protocol
ISATAP	Intra-Site Automatic Tunnel Addressing Protocol
ISDN	Integrated Services Digital Network
I-SID	Backbone Service Instance Identifier
IS-IS	Intermediate System-to-Intermediate System
ISO	International Organization for Standardization
ISP	Internet Service Provider

ISPF	Incremental Shortest Path First
ISSU	In-Service Software Upgrade
IST	Internal Spanning Tree
ITA	Intelligent Target Accounting
ITR	Ingress Tunnel Router
ITSP	Internet Telephone Service Provider
ITU	International Telecommunication Union
ITU-T	International Telecommunication Union Telecommunication
IV	Initialization Vector
IVR	Interactive Voice Response
K	Return
KAT	Known-Answer Test
KCK	EAPOL-Key Confirmation Key
KEK	Key Encrytion Key
KEK	EAPOL-Key Encryption Key
KS	Key Server
L	Return
L2F	Layer 2 Forwarding
L2PT	Layer 2 Protocol Tunneling
L2TP	Layer 2 Tunneling Protocol
L2VPN	Layer 2 Virtual Private Network
L3VNI	Layer 3 VNI
L3VPN	Layer 3 Virtual Private Network
LAC	L2TP Access Concentrator
LACP	Link Aggregation Control Protocol
LACPDU	Link Aggregation Control Protocol Data Unit
LAN	Local Area Network
LB	Loopback
LB	Label Base
LB	Load Balance
LBM	Loopback Message
LBR	Loopback Reply
LC	Logic Channel
LCFO	Loop Current Feed Open
LCI	Logic Channel Identifier
LCP	Link Control Protocol
LDAP	Lightweight Directory Access Protocol
LDN	Local Dialing Number
LDP	Label Distribution Protocol

LDP ID	LDP Identifier
LDPC	Low-Density Parity Check
LER	Label Edge Router
LFI	Link Fragmentation and Interleaving
LFIB	Label Forwarding Information Base
LGS	Loop-start & Ground-start Signaling
LHR	Last-Hop Router
LI	Leap Indicator
LLC	Logical Link Control
LLDP	Link Layer Discovery Protocol
LLDPDU	Link Layer Discovery Protocol Data Unit
LLDP-MED	Link Layer Discovery Protocol Media Endpoint Discovery
LLID	Logical Link ID
LLQ	Low Latency Queuing
LM	Loss Measurement
LMI	Local Management Interface
LMM	Loss Measurement Message
LMR	Loss Measurement Reply
LNS	L2TP Network Server
LO	Label-block Offset
LOCV	Loss of Connectivity Verification defect
LOID	Logical ONU Identifier
LoRaWAN	Long Range Wide Area Network
LOS	Loss of Signal
LPU	Line Processing Unit
LPU Port	Line Processing Unit Port
LQR	Link Quality Reports
LR	Line Rate
LR	Label Range
LS	Link State
LSA	Link State Acknowledgment
LSA	Link State Advertisement
LSAck	Link State Acknowledgment
LSDB	Link State Database
LSDB	Link State DataBase
LSN	Large-scale NAT
LSP	Label Switched Path
LSP	Link State PDU
LSPDU	Link State Protocol Data Unit
LSR	Link State Request

LSR	Link State Record
LSR	Label Switching Router
LSU	Link State Update
LT	Linktrace
LTM	Linktrace Message
LTR	Linktrace Reply
LTS	L2TP Tunnel Switch
LVF	Listening Virtual Forwarder
LZ	Lempel-Ziv compression
M	Return
M flag	Managed Address Configuration Flag
MA	Mobility Agent
MA	Maintenance Association
MAC	Message Authentication Code
MAC	Media Access Control
MACsec	Media Access Control Security
MAD	Multi-Active Detection
MAM	Maximum Allocation Model
MAN	Metropolitan Area Network
MAP	Mesh Access Point
MBGP	Multicast BGP
MBS	Maximum Burst Size
MC	Mobility Controller
MCC	Mobile Country Code
MCE	Multi-VPN-Instance Customer Edge
MCS	Modulation and Coding Scheme
MCU	Multipoint Control Unit
MD	Maintenance Domain
MD	Multicast Domain
MDC	Multitenant Device Context
MDI	Medium Dependent Interface
MDL	Maintenance Data Link
mDNS	Multicast DNS
MDT	Multicast Distribution Tree
ME	Maintenance Entity
MEC	Multi-access Edge Computing
MED	Multi-Exit Discriminator
MEG	Maintenance Entity Group
MEP	Maintenance association End Point

MEP	MEG End Point
MFAS	Multiframe FAS
MFC	Multi-Frequency Compelled
MFF	MAC-Forced Forwarding
MFR	Multilink Frame Relay
MGCP	Media Gateway Control Protocol
mGRE	Multipoint Generic Routing Encapsulation
MIB	Management Information Base
MIC	Message Integrity Check
MIMO	Multiple Input, Multiple Output
MIP	Maintenance association Intermediate Point
MIP	Mobile IP
MKA	MACsec Key Agreement
MKD	Mesh Key Distributor
MKI	Master Key Identifier
MLD	Multicast Listener Discovery Protocol
MLD Snooping	Multicast Listener Discovery Snooping
MLSP	Mobile Link Switch Protocol
MME	Management MIC IE
MNC	Mobile Network Code
MoH	Music on Hold
MOS	Mean Opinion Scores
MOTD	Message of The Day
MP	Maintenance Point
MP	Mesh Point
MP	Merge Point
MP_REACH_NLRI	Multiprotocol Reachable NLRI
MP_UNREACH_NLRI	Multiprotocol Unreachable NLRI
MP-BGP	Multiprotocol Border Gateway Protocol
MPCP	Multipoint Control Protocol
MPDU	MAC Protocol Data Unit
MPE	Middle-Level PE
MPLS	Multiprotocol Label Switching
MPLS SR	Segment Routing with MPLS
MPLS TE	Multiprotocol Label Switching Traffic Engineering
MPLS VPN	MPLS Virtual Private Network
MPLS-TP	MPLS Transport Profile
MPP	Mesh Portal Point
MQC	Model QoS Command
MR	Map Resolver

MR	Merge Request
MRIB	Multicast Routing Information Base
MRP	Multiple Registration Protocol
MRPDU	MRP Protocol Data Unit
MRRA	Merge Request Resource Allocation
MRU	Maximum-Receive-Unit
MS	Manual Switch
MS	Map Server
MSCHAP	Microsoft Challenge Handshake Authentication Protocol
MSDP	Multicast Source Discovery Protocol
MSDU	MAC Service Data Unit
MSK	Multicast Session Key
MSOH	Multiplex Section Overhead
MSS	Maximum Segment Size
MSTI	Multiple Spanning Tree Instance
MSTP	Multiple Spanning Tree Protocol
MT	Multicast Tunnel
MTI	Multicast Tunnel Interface
MTP	Maintain Probe
MTR	Multi-Topology Routing
MTU	Maximum Transmission Unit
MTU-s	Multi-Tenant Unit switch
MU	Mobile Unit
MVPN	Multicast Virtual Private Network
MVRP	Multiple VLAN Registration Protocol
MVXLAN	Multicast VXLAN
MWI	Message Waiting Indication
MX	Mail Exchanger
N	Return
NA	Neighbor Advertisement
NAI	Network Access Identifier
NAPT	Network Address Port Translation
NAPT-PT	Network Address Port Translation-Protocol Translation
NAS	Network Access Service
NAS	Network Access Server
NAS-ID	Network Access Server Identifier
NAS-Port-ID	Network Access Server Port Identifier
NAS-VLAN-ID	Network Access Server VLAN Identifier
NAT	Network Address Translation

NAT-PT	Network Address Translation-Protocol Translation
NBAR	Network Based Application Recognition
NBMA	Non-Broadcast Multi-Access
NCP	Network Control Protocol
ND	Neighbor Discovery
NDA	NetStream Data Analyzer
NDE	NetStream Data Exporter
NDP	Neighbor Discovery Protocol
NDPP	Network Device Protection Profile
NE	Network Element
NEMO	Network Mobility
NET	Network Entity Title
NetBIOS	Network Basic Input/Output System
NETCONF	Network Configuration Protocol
NFAS	non–FAS
NFV	Network Function Virtualisation
NHLFE	Next Hop Label Forwarding Entry
NHRP	Next Hop Resolution Protocol
NI	National ISDN
NIB	Nexthop Information Base
NII	Network International Identifier
NIST	National Institute of Standards and Technology
NIT	Not Initial Terminal
NLB	Network Load Balancing
NLBS	Network Load Balancing Service
NLPID	Network Layer Protocol Identifier
NLRI	Network Layer Reachability Information
NM	Network Management
NMFAS	Non-Multiframe FAS
NMS	Network Management Station
NMS	Network Management System
NMS	Network Management Server
NNI	Network-to-Network Interface
NO-PAT	Not Port Address Translation
NPDU	Network Protocol Data Unit
NPE	Network Provider Edge
NPTv6	IPv6-to-IPv6 Network Prefix Translation
NPV	N_Port Virtualization
NQA	Network Quality Analyzer
NR	No Request

nrt-VBR	non-real-time Variable Bit Rate
NS	Neighbor Solicitation
NS	Name Server
NSAP	Network Service Access Point
NSC	NetStream Collector
NSF	Non-Standard Facilities
NSR	Nonstop Routing
NSS	Number of Spatial Streams
NTDP	Neighbor Topology Discover Protocol
NTE	Named Telephone Event
NTP	Network Time Protocol
NTT	Nippon Telegraph and Telephone Corpration
NVC	Network Virtualization Controller
NVE	Network Virtualization Edge
NVGRE	Network Virtualization using Generic Routing Encapsulation
O	Return
O Flag	Other Stateful Configuration Flag
OAA	Open Application Architecture
OAMPDU	OAM Protocol Data Unit
OAP	Open Application Platform
OC	Optical Carrier
OC	Ordinary Clock
ODAP	On-Demand Address Pool
ODF	Optical Distribution Frame
ODN	Optical Distribution Network
ODU	Optical Data Unit
OEM	Original Equipment Manufacturer
OFDM	Orthogonal Frequency Division Multiplexing
OI	Organization Identifier
OID	Object Identifier
OLT	Optical Line Terminal
ONU	Optical Network Unit
OOB	Out-of-Band
OPU	Optical Payload Unit
ORF	Outbound Route Filtering
OSI	Open System Interconnection
OSPF	Open Shortest Path First
OSU	Online Sign Up
OTN	Optical Transport Network

OTU	Optical Transmit Unit
OUI	Organizationally Unique Identifier
OVSDB	Open vSwitch Database
P	Return
P2MP	Point-to-MultiPoint
P2P	PW to PW
P2P	Peer-to-Peer
P2P	Point-to-Point
P2PTC	Peer-to-Peer Transparent Clock
PA	Provider Allocated
PADT	PPPoE Active Discovery Terminate
PAGP	Port Aggregation Protocol
PAM	Port to Application Map
PAM	Pulse Amplitude Modulation
PAN ID	Personal Area Network Identifier
PAP	Password Authentication Protocol
Passive-Stateful PCC	Passive-Stateful Path Computation Client
Passive-Stateful PCE	Passive-Stateful Path Computation Element
PAT	Port Address Translation
PBAR	Port Based Application Recognition
PBB	Provider Backbone Bridge
PBBN	Provider Backbone Bridge Network
PBN	Provider Bridge Network
PBR	Policy-based Routing
PBX	Private Branch Exchange
PCB	Protocol Control Block
PCC	Path Computation Client
PCE	Path Computation Element
PCEP	Path Computation Element Communication Protocol
PCM	Pulse Code Modulation
PCR	Peak Cell Rate
PD	Powered Device
PD	Prefix Delegation
PDH	Plesiochronous Digital Hierarchy
PDP	Policy Decision Point
PDU	Protocol Data Unit
PE	Provider Edge
PE-agg	PE Aggregation
PEAP	Protected Extensible Authentication Protocol

PEAP-GTC	Protected Extensible Authentication Protocol-Microsoft Generic Token Card
PEAP-MSCHAPv2	Protected Extensible Authentication Protocol-Microsoft Challenge Handshake Authentication Protocol v2
PEM	Privacy Enhanced Mail
PEM	Power Entry Module
PEP	Policy Enforcement Point
PFC	Power Free Connector
PFC	Priority-based Flow Control
PFC	Protocol-Field-Compression
PFS	Perfect Forward Secrecy
PHB	Per-hop Behavior
PHP	Penultimate Hop Popping
PI	Power Interface
PI	Provider Independent
PI	Progress Indicator
PIC	Prefix Independent Convergence
PIM	Protocol Independent Multicast
PIM Snooping	Protocol Independent Multicast Snooping
PIM-DM	Protocol Independent Multicast-Dense Mode
PIM-SM	Protocol Independent Multicast-Sparse Mode
PIM-SSM	Protocol Independent Multicast Source-Specific Multicast
PIN	Personal Identification Number
PIR	Peak Information Rate
PKCS	Public Key Cryptography Standards
PKI	Public Key Infrastructure
PLCP	Physical Layer Convergence Procedure
PLMN	Public Land Mobile Network
PLR	Point of Local Repair
PMK	Pairwise Master Key
PMTU	Path MTU
PoE	Power over Ethernet
POH	Path Overhead
POP3	Post Office Protocol - Version 3
POS	Passive Optical Splitter
POS	Point of Sale
PPP	Point-to-Point Protocol
PPPoA	PPP over ATM
PPPoE	Point-to-Point Protocol over Ethernet
PPPoEoA	PPPoE over ATM

PPTP	Point-to-Point Tunneling Protocol
PQ	Priority Queuing
PRBS	Pseudo Random Bit Sequence
PRC	Primary Reference Clock
PRI	Primary Rate Interface
PRL	Preferred Roaming List
PS	Protection Switching
PSB	Path State Block
PSC	Protection State Coordination
PSD	Power Spectral Density
PSE	Power Sourcing Equipment
PSK	Pre-Shared Key
PSN	Packet Switched Network
PSNP	Partial Sequence Number PDU
PSST	Principal Switch Selection Timer
PSTN	Public Switched Telephone Network
PTK	Pairwise Transient Key
PTP	Precision Time Protocol
PTR	Pointer Record
PTY	Pseudo-Terminals
PUK	PIN Unlocking Key
PVC	Permanent Virtual Circuit
PVC PQ	PVC Priority Queuing
PVID	Port VLAN ID
PVP	Permanent Virtual Path
PVST	Per-VLAN Spanning Tree
PW	Pseudowire
PW-ACH	PW Associated Channel Header
PWCT	Pairwise Conditional Test
PWE3	Pseudo Wire Emulation Edge-to-Edge
PXE	Preboot eXecution Environment
Q	Return
QCN	Quantized Congestion Notification
QL	Quality Level
QoS	Quality of Service
QPPB	QoS Policy Propagation Through the Border Gateway Protocol
R	Return
RA	Router Alert
RA	Router Advertisement

RA	Registration Authority
RADIUS	Remote Authentication Dial-In User Service
RAI	Remote Alarm Indication
RALM	RADIUS Authenticated Login Using MAC-address
R-APS	Ring Automatic Protection Switching
RAS	Registration, Admission, and Status
RB	Routing Bridge
RBAC	Role Based Access Control
RBM	Remote Backup Management
RCA	Release Change Authorization
RCF	Reconfigure Fabric
RCPI	Received Channel Power Indicator
RD	Routing Domain
RD	Reported Distance
RD	Route Distinguisher
RDI	Remote Defect Indication
RDM	Russian Dolls Model
RDP	Read Diagnostic Parameters
RED	Random Early Detection
RedisDBM	Redis Database Manager
REG	Registration Center
RFID	Radio Frequency Identification
RIB	Routing Information Base
RIP	Routing Information Protocol
RIP-2	Routing Information Protocol version 2
RIPng	RIP next generation
RIR	Resilient Intelligent Route
RLOC	Routing Locator
RLSN	Remote Link Status Notification
RMON	Remote Network Monitoring
ROA	Recognized operating Agency
Roam OI	Roam Organization Identifier
RP	Rendezvous Point
RP	Reflective Relay
RP	Reaction Point
RPA	Register Port Attributes
RPA	Rendezvous Point Address
RPC	Remote Procedure Call
RPF	Reverse Path Forwarding
RPI	Receive Power Indication

RPKI	Resource Public Key Infrastructure
RPL	Rendezvous Point Link
RPL	Ring Protection Link
RPR	Resilient Packet Ring
RPRT	Register Port
RPS	Redundant Power System
RP-Set	Rendezvous Point Set
RPT	Rendezvous Point Tree
RR	Route Reflector
RR	Reflective Relay
RR	Router Renumber
RRI	Reverse Route Injection
RRM	Radio Resource Management
RRPP	Rapid Ring Protection Protocol
RS	Router Solicitation
RSB	Reservation State Block
RSCN	Registered State Change Notification
RS-DCC	Resource-Shared DCC
RSH	Remote Shell
RSN	Robust Security Network
RSNA	Robust Security Network Association
RSNI	Received Signal to Noise Indicator
RSOH	Regenerator Section Overhead
RSSI	Received Signal Strength Indicator
RSSI	Received Signal Strength Indication
RSTP	Rapid Spanning Tree Protocol
RSVP	Resource Reservation Protocol
RT	Route Target
RTC	Remote Terminal Connection
RTCP	Real-Time Transport Control Protocol
RTM	Real-Time Event Manager
RTP	Reliable Transport Protocol
RTP	Real-Time Transport Protocol
RTPQ	Real-Time Transport Protocol Priority Queuing
RTS	Request to Send
RTSP	Real Time Streaming Protocol
RTT	Round-Trip Time
rt-VBR	Real-time Variable Bit Rate
RU	Rack Unit

S	Return
S/MIME	Secure/Multipurpose Internet Mail Extensions
SA	Security Association
SA	Source Active
SA Query	Security Association Query
SABM	Set Asynchronous Balanced Mode
SACK	Selective Acknowledgment
SAE	Simultaneous authentication of equals
SAFI	Subsequent Address Family Identifier
SAII	Source Attachment Individual Identifier
SAM	Security Accounting Management
SAN	Storage Area Networks
SAP	Service Advertising Protocol
SAToP	Structure-Agnostic TDM over Packet
SAVI	Source Address Validation Improvement
SB	Service Bridge
SBFD	Seamless BFD
SBM	Subnetwork Bandwidth Management
SCCP	Skinny Client Control Protocol
SCEP	Simple Certificate Enrollment Protocol
SCFF	Single Choke Fairness Frame
SCR	Sustainable Cell Rate
SCR	State Change Registration
SD	Signal Degrade
SDH	Synchronous Digital Hierarchy
SDLC	Synchronous Data Link Control
SDN	Software Defined Network
SDP	Session Description Protocol
SDSL	Symmetric Digital Subscriber Line
SDU	Service Data Unit
SE	Shared-Explicit
SEC	SDH Equipment Clock
SF	Super Frame
SF	Signal Fail
SFC	Stage Fabric Configuration Update
sFlow	Sampled Flow
SFM	Source-Filtered Multicast
SFP	Small Form-factor Pluggable
SFTP	Secure FTP

Short GI	Short Guard Interval
SIA	Stuck In Active
SID	Segment Identifier
SIP	Session Initiation Protocol
SIPS	SIP Secure
SLA	Service Level Agreement
SLAAC	Stateless Address Autoconfiguration
SLB	Server Load Balance
SLC	Service Logic Control
SLIP	Serial Line Internet Protocol
SLM	Single-ended Loss Measurement
SMA	State Machine based Anti-spoofing
SmartMC	Smart Management Center
SMET	Selective Multicast Ethernet Tag Route
S-MLAG	Simple Multichassis Link Aggregation
SMTP	Simple Mail Transfer Protocol
SN	Serial Number
SNA	System Network Architecture
SNAP	Subnet Access Protocol
SNAT	Source Network Address Translation
SNMP	Simple Network Management Protocol
SNMP-DCA	SNMP Data Collection Agent
SNP	Sequence Number PDU
SNPA	Subnetwork Point of Attachment
SNR	Signal-to-Noise Ratio
SNTP	Simple NTP
SOA	Start of Authority
SOAP	Simple Object Access Protocol
SOH	Section Overhead
SONET	Synchronous Optical Network
SoO	Site of Origin
SP	Strict Priority
SP	Service Provider
SP	Scheduler Policy
SPB	Shortest Path Bridging
SPBM	Shortest Path Bridging MAC Mode
SPBM	Shortest Path Bridging MAC
SPBN	Shortest Path Bridging Network
SPCS	Stored Program Control Switching System
SPE	Superstratum PE or Service Provider-end PE

SPF	Shortest Path First
SPI	Security Parameter Index
SPID	Service Profile Identification
SPM	Smart PoE Manager
SPSource ID	Shortest Path Source Identifier
SPT	Shortest Path Tree
SQL	Structured Query Language
SR	Segment Routing
Srefresh	Summary Refresh
SRGB	Segment Routing Global Block
SRLB	Segment Routing Local Block
SRLSP	Segment Routing Label Switched Path
SRMC	Segment Routing Mapping Client
SRMS	Segment Routing Mapping Server
SRST	Survivable Remote Site Telephony
sr-TCM	single rate TCM
SRTP	Secure Real-Time Transport Protocol
SRV	Service
SSA	SIP Stack Adapt
SSH	Secure Shell
SSID	Service Set Identifier
SSL	Secure Sockets Layer
SSM	Synchronization Status Message
SSM	Source-Specific Multicast
SSP	Switch-to-Switch Protocol
SSU-A	primary level SSU
SSU-B	second level SSU
ST	Shared Tree
Stateful PCE	Stateful Path Computation Element
Stateless PCC	Stateless Path Computation Client
Stateless PCE	Stateless Path Computation Element
STBC	Space-Time Block Coding
STP	Spanning Tree Protocol
STR	Switch Trace Route
SVC	Static Virtual Circuit
SVC	Switched Virtual Circuit
SVP	SpectraLink Voice Priority
T	Return
TA	Terminal Adapter

TACACS	Terminal Access Controller Access Control System
TACL	Temporary Access Control List
TAI	International Atomic Time
TAII	Target Attachment Individual Identifier
T-BC	Telecom Boundary Clock
TC	Topology Checksum
TC	Topology Change
TC	Topology client
TC	Traffic Class
TC	Transparent Clock
TCA	Topology Change Acknowledge
TCAM	Ternary Content Addressable Memory
TCI	Tag Control Information
Tcl	Tool Command Language
TCN BPDU	Topology Change Notification BPDU
TCP	Transmission Control Protocol
TCT-BC	Transparent Telecom Boundary Clock
TDM	Time Division Multiplexing
TDMA	Time Division Multiple Access
TE	Traffic Engineering
TEDB	TE DataBase
TEI	Terminal Endpoint Identifier
TEID	Tunnel Endpoint Identifier
TEK	Tranfic Encrytion Key
TFO	Transport Flow Optimization
TFTP	Trivial File Transfer Protocol
TI-LFA FRR	Topology-Independent Loop-free Alternate Fast Reroute
TIM	Traffic Indication Map
TK	Temporal Key
TKIP	Temporal Key Integrity Protocol
TLS	Transport Layer Security
TLS	Transparent LAN Service
TLV	Type/Length/Value
TM	Topology Master
ToS	Type of Service
TP	Traffic Policing
TP	Topology Protection
TPA	Third-part Application
TPC	Transmit Power Control
TPDU	Transport Protocol Data Unit

TPID	Tag Protocol Identifier
TPMR	Two-Port MAC Relay
TQ	Time Quantum
TRILL	TRansparent Interconnection of Lots of Links
TRIP	Triggered RIP
tr-TCM	two-rate TCM
TS	Traffic Shaping
TSA	Tunnel Switching Aggregator
TST	Test
T-TC	Telecom Transparent Clock
TTI	Trail Trace Identifier
TTL	Time to Live
TTLS	Tunneled Transport Layer Security
TTLS-GTC	Tunneled Transport Layer Security-Microsoft Generic Token Card
TTLS-MSCHAPv2	Tunneled Transport Layer Security-Microsoft Challenge Handshake Authentication Protocol v2
T-TSC	Telecom Time Slave Clock
TTY	True Type Terminal
TU	Tributary Unit
TUG	Tributary Unit Group
TWAMP	Two-Way Active Measurement Protocol
TxBF	Tx Beamforming
TXOP Limit	Transmission Opportunity Limit
TXT	Text
U	Return
UA	Unnumbered Acknowledge
UA	User Agent
UAC	User Agent Client
U-APSD	Unscheduled Automatic Power-Save Delivery
UAS	User Agent Server
UBR	Unspecified Bit Rate
UCM	User Connection Management
UDLD	Uni-directional Link Direction
UDP	User Data Protocol
UE	User Equipment
UFC	Update Fabric Configuration
UIM	User Identity Module
UNI	User-to-Network Interface
UNI	User Network Interface

UPE	User facing-Provider Edge
UPE	Underlayer PE or User-end PE
URI	Uniform Resource Identifier
URL	Uniform Resource Locator
uRPF	Unicast Reverse Path Forwarding
USK	Unicast Session Key
USM	User-Based Security Model
UTC	Coordinated Universal Time
UTM	Unified Threat Management
V	Return
V2V	Video to Video
VA	Virtual Access
VACM	View-based Access Control Model
VAD	Voice Activity Detection
VAM	VPN Address Management
VBR-NRT	Variable Bit Rate-Non Real Time
VBR-RT	Variable Bit Rate-Real Time
VC	Virtual Circuit
VC	Virtual Container
VCC	Virtual Circuit Connection
VCCV	Virtual Circuit Connectivity Verification
VCF	Vertical Converged Framework
VCFC	VCF Controller
VCI	Virtual Channel Identifier
VCN	Virtual Circuit Number
VCPM	Voice Co-processing Module
VD	Virtual Device
VDP	VSI Discovery and Configuration Protocol
VDSL	Very high-speed Digital Subscriber Line
VE	Virtual Ethernet
VE-Bridge	Virtual Ethernet Bridge
VEth	Virtual Ethernet
VF Owner	Virtual Forwarder Owner
VFW	Virtual Firewall
VLAN	Virtual Local Area Network
VM	Virtual Machine
VMM	Virtual Machine Management
VN	Version Number
VNC	Virtual Network Computing

VNI	VXLAN Network Identifier
VoD	Video on Demand
VoIP	Voice over IP
VP	Virtual Path
VPC	Virtual Path Connection
VPC	Virtual Private Cloud
VPDN	Virtual Private Dial-up Network
VPI	Virtual Path Identifier
VPLS	Virtual Private LAN Service
VPM	Voice Processing Module
VPN	Virtual Private Network
VPWS	Virtual Private Wire Service
VR	Virtual Router
VRF	Virtual Routing and Forwarding
VRRP	Virtual Router Redundancy Protocol
VSAN	Virtual Storage Area Network
VSD	Virtual Security Domain
VSI	Virtual Switch Instance
VSI	Virtual Station Interface
VSID	Virtual Subnet Identifier
VSIP	Virtual Service IP
VSRP	Virtual Service Redundancy Protocol
vSwitch	Virtual Switch
VT	Virtual Template
VTEP	VXLAN Tunnel End Point
VTP	VLAN Trunking Protocol
VTY	Virtual Type Terminal
VXLAN	Virtual eXtensible LAN
VXLAN-DCI	VXLAN Data Center Interconnection
W	Return
WAAS	Wide Area Application Services
WAF	Web Application Firewall
WAI	WLAN Authentication Infrastructure
WAN	Wide Area Network
WAP	Wireless Application Protocol
WAPI	WLAN Authentication and Privacy Infrastructure
WASS	Wide Area Application Services
WDS	Wireless Distribution System
WEP	Wired Equivalent Privacy

WFQ	Weighted Fair Queuing
WHA	WLAN High Availability
WIDS	Wireless Intrusion Detection System
WiNet	Wisdom Network
WINS	Windows Internet Naming Service
WIPS	Wireless Intrusion Prevention System
WLAN	Wireless Local Area Network
WLAN RRM	Radio Resource Management
WMM	Wi-Fi Multimedia
WPA	Wi-Fi Protected Access
WPAD	Web Proxy Auto-Discovery
WPI	WLAN Privacy Infrastructure
WRED	Weighted Random Early Detection
WRR	Weighted Round Robin
WSA	Wireless Spectrum Analysis
WT	Wireless Terminator
WTU	Wireless Terminator Unit
WWN	World Wide Name
X	Return
XFP	10-Gigabit Small Form-factor Pluggable
XML	Extensible Markup Language
XSD	XML Schema Document
XSD	XML Schema Definition
Z	Return
ZBR	Zone Border Router
